Analytical Equipment**

CUR-H06846-307-R434

Improve your image with dedicated microscopes.

Focus on Philips.

Philips has taken the advanced design concepts successfully pioneered in the EM 400 electron microscope and created a family of three instruments. Each of these new microscopes satisfies specific application needs of researchers in different sectors of the scientific research community.

Biologists, pathologists and life scientists will appreciate the EM 410LS' qualities of high brightness and contrast when it comes to investigating their most demanding specimens. The EM 410LS combines ease of operation and ease of registration with an optical system maximized for both traditional thin section and thick section stereological studies.

In applied research, the EM 420 integrated analytical system exploits the second generation twin objective lens to meet the demanding requirements of high resolution and high specimen tilt, and provides excellent elemental analysis and diffraction capabilities. This concept is primed and ready to meet each information challenge as it comes and is designed to function in the multi-user, high throughput conditions prevalent in today's research environment.

Philips now offers the world's first 300 kV analytical electron microscope. The EM 430 is a unique combination of "Twin Lens" optics with the inherent benefits of the shorter wavelength. This provides significant advantages in penetration, with higher imaging and spatial resolution and increased analytical sensitivity.

Focus on Philips for electron microscopes that match your research needs. Call or write: Philips Scientific & Analytical Equipment, Electron Optics Department, TQ-III-4, Eindhoven, The Netherlands. Tel.: (040) 788519. In the U.S.A.: Philips Electronic Instruments, Electron Optics Group, 85 McKee Drive, Mahwah, NJ 07430. Tel.: (201) 529-3800.

**Opening new roads of exploration—
Introducing the ultimate research microscopes—
Nikon's Microphot Series.**

Nikon's all-new Microphot Series—the Microphot-FX and Microphot—bring the future closer to a wide variety of research pursuits. However varied and diverse your research aims, the Microphot Series, along with Nikon's unmatched line of accessories and attachments, will offer you a system perfectly suited to your needs.

When you say "why FPLC" you are half way there...

... because Superose™ from Pharmacia is the peak of evolution in high performance gel filtration for the separation of labile biomolecules.

Over the past 25 years, Pharmacia has developed a broad range of chromatography media, including Sephadex®, Sepharose®, Sephacryl®, MonoBeads™, ProRPC™, and PepRPC™, together with the FPLC System, to meet the ever-growing requirements of experienced, innovative and demanding groups of researchers throughout the world.

Now, the FPLC System and Superose from Pharmacia allow you to use high performance gel filtration without the limitations imposed by silica and stainless steel.

With the introduction of Superose, the Pharmacia range of high performance chromatography media, including MonoBeads, ProRPC and PepRPC, has been extended to provide you with gel filtration media for fast, high resolution separations of biomolecules, from small peptides to large proteins and DNA-fragments.

- High performance prepacked glass columns
- Reproducible results
- High recovery of biological activity
- pH stability (1-14)
- Extended column life
- Pharmacia know-how

... so go all the way

Superose pre-packed glass columns with high chemical and pH stability, up to pH 14, provide you with unequalled flexibility in your choice of eluents and greatly simplify your column cleaning routines.

Superose allows you to perform rapid separations (20-60 min) while obtaining high resolution and high recovery, facilitating and improving your work in research, quality control or process development.

Superose has been especially developed for bioscientists and is optimized for high performance separation of proteins, DNA-fragments, peptides and other biomolecules.

DYNAMIC HOLOGRAPHY

IMAGE ANALYSIS
& MICROCOPY
product review

A single polarized 633-nm He:Ne laser beam enters a photorefractive BaTiO₃ crystal in a glass cuvette. Multiple reflections from dynamic holograms written in the crystal with scattered light cause the beam to bend and fan out, eventually splitting into two. A phase-conjugate beam propagates back to the laser and is a time-reversed replica of the original beam. See News and Views, page 12.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

GUIDE TO AUTHORS

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc., should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc., should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.

See what 33 years
of our research
can do for yours.

Announcing the new CALBIOCHEM® catalog. Three decades in the making, it has become the biochemicals and immunochemicals better idea book. Now it's bigger and better than ever.

We started work on the 1985 catalog in 1952. That was when CALBIOCHEM® researchers began pushing the state of the art to produce biochemical and immunochemical products never before available to research

laboratories.

Now over 2000 products later, CALBIOCHEM® is the brand name you find on some of the finest research chemicals advanced technology can produce. Many of them are available nowhere else.

Good reason why you should keep the CALBIOCHEM® catalog close at hand. It's a reference guide to top quality products that contains a wealth of technical information.

The 1985 CALBIOCHEM® catalog is worth its weight in gold to advanced researchers. But you can have your own personal copy for a very modest price:

Free for the asking.

See what 33 years of our research can do for yours. Circle the reader service number or call your CALBIOCHEM® sales representative today for your copy of the 1985 CALBIOCHEM® catalog.

Arms control.

λ gt 11 Arms

Expression Cloning. The λ gt 11 Cloning Vector has been digested with EcoRI and dephosphorylated. It accepts 0 to 7 Kilobase EcoRI inserts.

Kits contain strains Y1088, Y1089, Y1090 and a test insert. Efficiencies are greater than 10^7 recombinants per microgram of λ gt 11 Arms using Gigapack™ packaging extract.

λ gt 10 Arms

Genetic Selection. The λ gt 10 Cloning Vector is suited for the cloning of EcoRI ligatable DNA fragments that range between 0 and 7 kilobases. Kits contain strains C600 and C600 Hfl+ and a test insert. Efficiencies are greater than 10^7 recombinants per microgram of λ gt 10 Arms using Gigapack.

EMBL3 Arms

Large Insert, Genetic Selection. The EMBL3 Cloning Vector is one of the most versatile and efficient lambda-based vectors available today. Its advantages include the ability to accept BAM HI ligatable inserts (i.e. Mbo I, Sau 3A, Bgl II or BAM HI inserts up to 22kb in length), strains Q358, Q359 and a test insert are provided. Efficiencies range between 2×10^6 and 8×10^6 recombinants per microgram of EMBL3 Arms using Gigapack packaging extract.

λ gt 11, λ gt 10 and EMBL3 Cloning Vectors save valuable time and have been expressly processed to be extraordinarily effective, reliable and inexpensive. Simplicity in protocol make Vector Cloning Systems products a convenience to work with.

SAVANT'S HIGH SPEED TABLE TOP CENTRIFUGE

Recirculating Water Cooler...and In-Line Heater

RWC
Recirculating
Water Cooler

Extended capability when used with the recirculating water cooler for **COOLING** the centrifuge chamber and with the in-line heater for **HEATING** the chamber and holding it at a constant temperature...The better way to achieve greater efficiency and precision when concentrating and measuring biologically active compounds.

In-Line Heater

High-Speed
Centrifuge

A TABLE TOP UNIT WITH FLOOR MODEL CAPABILITY

- 10,000 RPM (Max)
- 12,800 RCF (Max)
- Table Top
- Full Visibility Cover
- Automatic Braking
- 25 Minute Timer
- Heat Exchanger Coil for Cooling and Heating Chamber
- Special Microfilter Tubes
- 12 x 75 Tubes
- 17 x 95 Tubes
- MC Tubes
- Mechanical Lock
- Variable Speed

The **Heat Exchanger** coil is a unique feature; circulating controlled temperature water in order to cool or heat the chamber to prevent samples from overheating...or for the maintenance of temperature below or above ambient in order to maintain the stability of biologically active components.

No need to go into the cold room since the centrifuge can be kept close by on a laboratory bench.

Unnecessary noise pollution is eliminated because the centrifuge is surprisingly quiet by comparison with other well known makes.

Indicator Strips

for pH measurements
in all aqueous solutions

- easy to read due to the contrast effects of the reaction zones
- clear color differences between the pH intervals
- good light-fastness
- very accurate pH measurements even in weakly buffered solutions
- pH measurements can be made in colored or turbid solutions, because the strips can be briefly rinsed under water, after dipping, with no color change
- no bleeding of the dyes

Indicator strips are supplied for the various pH ranges at different intervals.

Please ask for our brochure.

European setback at Milan

Disagreement among members of the European Communities last weekend at Milan will hamper the cause of technical collaboration. Modest plans are now in order.

ALL the high hopes of the past several weeks that Europe would find a way of making itself technologically competitive with the rest of the world have been thrown into limbo. That is the simplest reading of the chaos into which the affairs of the European Communities have been plunged by last weekend's summit meeting at Milan. Formally, the heads of government did manage to agree that something should be done to put flesh on the bones of the French Eureka project; the French government is to call a meeting of foreign and research ministers in the second half of this month at which they will attempt to decide how the Eureka enterprise should work. The present plan is that governments other than the twelve members and putative members of the Communities should be free to participate if they wish. (Austria, Sweden and Switzerland are likely to be welcomed as outsiders.) The meeting is not intended to choose projects for collaboration but, rather, to define a mechanism which, governments agreed at Milan, should be above all flexible. The obvious snag is that while European governments are at loggerheads among themselves about the political future of their community, agreements on even technological collaboration are bound to seem unreal.

Ironically, the fiasco at Milan appears to have sprung from a sensible if belated recognition by European governments that the time has come to make what is often called the common market operate as such. Europe cannot be surprised that it is technologically often at a disadvantage in comparison with Japan and the United States when the present restraints on trade and competition persist. During the past few months, the European Commission has been hard at work on the definition of the steps that must be taken to dismantle these artificial and often illegal impediments to efficiency. Mercifully, all governments appear to agree that getting rid of these restrictions will be impossible while member states hang onto the principle that all decisions about the working of the Communities must be reached unanimously (or that any dissident member may veto an unpalatable proposal, as West Germany vetoed last month's agreement that cereal prices should be reduced). This is why the British went to Milan pushing for a package of procedural reforms that would have restricted a government's right to use the veto, and otherwise have made the community's decision-making more orderly. France and West Germany, on the other hand, with the unexpected backing of Italy, pushed instead for a revision of the Treaty of Rome, the legal instrument which is the foundation of the European Economic Community. The outcome is a fuzzy decision that, later in the year, there should be a formal conference to consider amendments to the treaty. This is a recipe both for delay and for further quarrelling within the community, if only because governments represented at this meeting will be able to veto any of the decisions it may reach. Especially because there is as yet no word on when or how the

conference will be organized, the upshot is bound to be that no framework for technological collaboration in Europe can be assured by the time of the Eureka meeting later this month.

Worse than that, the Milan meeting cannot but further sour relationships between European governments. Only occasionally in the past decade does it seem to have been possible for the heads of the European governments to meet without uncovering some obdurate disagreement. Last weekend's fracas at Milan will have further emphasized the degrees to which different members of the European Communities harbour different but serious reservations about the enterprise to which they belong. The European Communities have survived for the past thirty years chiefly because there has been a general recognition that attempts to force the pace towards European integration will be self-defeating if individual members are faced with politically unpalatable decisions. The attempt that will be made, later in the year, to force through amendments to the Treaty of Rome is bound to throw sand into the machinery of all kinds of European collaboration, Eureka included.

What can be salvaged from this mess? The best way forward for Eureka will be to postpone final decisions about the content of the programme of research and development on which Europe collectively seems eager to embark. In due course, it may emerge that there are technical projects of such originality that they promise opportunities for particular European industries to become genuinely competitive. Schemes for attempting to beat IBM at the game which it has played successfully over past decades should not, at this stage, qualify. It should also be clear that Eureka should not become one of those ambitious community projects in which there is some central pot of gold contributed by governments for a share of which companies in member states are encouraged to compete. The best strategy will be to use such public funds as there may be for supporting to provide the infrastructure from which novel technology may spring. Although President Mitterrand's clear wish (and political need) to clothe Eureka ambitiously would not be satisfied by, for example, public support for research and teaching institutions that could make good deficiencies in Europe, that may be the wisest course after the disaster at Milan. □

Where the onus lies

British science should make the government shoulder responsibility for political decisions.

ON the working hypothesis that the British government will not increase the funds earmarked for research in the next financial year (beginning in April 1986), researchers had better take what steps they can to save their own skins. In the next few months, the burden will fall chiefly on the Advisory Board for the Research Councils (ABRC), which technically exists to advise the Department of Education and Science on how the inadequate funds available should be divided. Two immediate issues must be settled. ABRC has to say how it would have the government respond to the report of the Kendrew Committee, which advocated a fortnight ago that Britain should pull out of European collaboration in high-energy physics (chiefly through CERN) unless there can be negotiated a 25 per cent reduction of the

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, it will be helpful if they will in future send **four copies of all manuscripts** offered for publication, either (as at present) to London or Washington.

common budget after 1991. Then, unexpectedly, a committee of the Royal Society on public support for geophysics (see *Nature*, 27 June, p. 709) has unexpectedly thrown up a series of questions about the Natural Environment Research Council (NERC) which cannot be ignored until the council itself decides the time has come to answer them. What should ABRC say?

The Kendrew strategy is unhelpful for the simple reason that it will yield no budgetary relief when that is needed most, which is now. Even if savings of the order of 25 per cent are possible, which is improbable when CERN members such as Italy are eager to see high-energy physics in Europe expand, the first small relief for the British budget would come only in 1988. The difficulty into which the whole Kendrew exercise was boxed is that Britain is committed to the present scale of spending at CERN for at least the next three years by the undertakings given by the Science and Engineering Research Council (SERC) that there would be no backsliding while the new accelerator is being built, by similar undertakings to the international collaborations building detectors for the new instrument and by the implicit, but equally important, undertakings to graduate students whose careers are predicated on the completion of projects such as these. If Britain now follows Kendrew's advice, the course of events during the next two years is easily predicted. There will be a long wrangle at Geneva about future budgets, Britain will be blamed for rocking what has hitherto been a united enterprise, but in the end (if the strategy is kept to) will be forced to withdraw in humiliation. The political damage done will be no less than if it were decided to pull out of CERN immediately, moral obligations notwithstanding.

This dilemma is not of the research community's making, nor is it one that the community should on its own resolve. The difficulty has arisen because, while the British government refuses to recompense the research councils for the fall in the value of sterling except on an *ad hoc* basis, the CERN subscription (now £35 million a year) has become conspicuous. (No doubt it is only a matter of time before some other committee is appointed to enquire into the cost of the British contribution to the La Palma observatory, inaugurated only last weekend.) ABRC should now firmly throw this problem at the government, which did at the outset of the Kendrew inquiry say that it would have the final say on any proposal to withdraw from CERN. Now is the time for that. ABRC should warn the government of the political risks of pulling out, should explain that it cannot ask members of the scientific community to embark on a probably futile negotiation when the execution of the implied duress is beyond its own control, and meanwhile should insist that this and the other politically sensitive international subscriptions which are at present part of the science budget (such as the SERC subscription to the European Space Agency) are taken off the books of the research councils and handled centrally, by ABRC itself, with proper safeguards against currency fluctuations. Failing a satisfactory reply, ABRC should decline to follow the Kendrew strategy, but instead ask SERC to fight for economies at CERN, to cut back on what it spends domestically on high-energy physics but not to raise the threat of withdrawal until more is known of the future pattern of spending. More constructively, the question might be rather whether the CERN agreement should be amended. Is it strictly necessary that national subscriptions should be determined only by gross national product?

The problem of NERC is also urgent. The argument that this research council, cobbled together in the 1960s, should now be broken up is strong (see *Nature* 311, 493; 1984) but is probably unpalatable to too many influential people. Last week's Royal Society document was only incidentally an inquiry into the research council's way of working, and as such is not sufficient basis for root-and-branch reform. But a few things should be clear. First, it is absurd that Britain should pull out of the Deep Sea Drilling Program because NERC's funds are otherwise committed. ABRC should issue the appropriate instruction. Second, it is a tragic waste of people that the British Geological Survey's staff should this year lack the funds to do scientific work

for similar reasons. The cause may be the unwillingness of other government departments to pay for commissioned research, but the Royal Society's committee is right to say that the British national interest requires continuity in this field. If the survey's work can be secured only by transferring it to some other branch of the British government, so be it. Finally, given the committee's cogent criticisms of NERC's record on the award of research grants to academic geophysicists, there is a strong case for transferring that part of its function lock, stock and barrel to SERC. This is what ABRC should be saying, and quickly. □

Waxman's way

The US Congress should abandon its scheme to set up two new research institutes.

THE US congressional calendar is once again burdened by Representative Henry Waxman's attempt to wish on the National Institutes of Health (NIH) two entirely unnecessary research institutes, one for arthritis and one for nursing. The outcome is predictable, and will be no different from what it has been in the past three years. Waxman's bill, which has already been passed by the House of Representatives, will in due course be sent off to the White House and vetoed by the President. This is what happened last year, and nobody expects the outcome to be any different this time. The explanation is simple enough. The administration thinks the two extra institutes unnecessary, and has said so. It is also suspicious of Waxman's motives. Although this year's version of the bill (like last year's) is a considerable retreat from the earlier versions that would have given Congress detailed control of the way the individual institutes of NIH spend their budgets, there is no reason to think that Waxman has abandoned his ambitions to strengthen congressional control of the NIH budget. But while this legislation lies in limbo, three of the institutes (including the National Cancer Institute) will have to limp along from year to year by means of a continuing resolution that gives the administration authority for a year to keep on spending at last year's rate.

This is hardly the way in which the US Congress, which over the years has been generous almost to a fault to NIH, should deal with its favoured dependants. But it is not likely that, if NIH is required to set up further institutes, the flow of funds from Congress will be increased? That is how supporters of Waxman-like legislations have argued in the past, urging that NIH should welcome the creation of one institute for each recognizably distinct disease. It goes without saying that the political benefits for those members of Congress who force on NIH institutes dedicated to the cure of particular diseases will be far from unimportant. But this suggestion that a symbiotic relationship between Congress and NIH would ultimately benefit both is offensive because it betokens a thorough misunderstanding of the way in which NIH functions.

Congress, its constituency in the United States and biomedical research internationally have hugely benefited from the flexibility with which NIH are organized. In the recent past, the contribution of people at the National Cancer Institute to the understanding of Acquired Immune Deficiency Syndrome (AIDS) would have been no greater if Congress had decreed four years ago that there should be a special institute devoted to this novel scourge. Nor would matters have been much improved if, using the powers to control institute budgets in detail which featured in earlier versions of Waxman's bill, Congress had insisted that teams at the National Cancer Institute should not let their curiosity wander beyond the field of potentially oncogenic viruses so as to encompass that which now appears responsible for AIDS. In short, the recipe of one institute for one disease is a recipe for rigidity in a system where flexibility has miraculously flourished, sometimes against the odds. That is what Mr Waxman, and his colleagues in the Congress, should now openly recognize. □

Soviet scientist

Nuclear winter expert vanishes without trace

Stockholm

A SOVIET computer scientist, who has played a leading part in the nuclear winter debate, disappeared from a meeting in Toledo, Spain, last March, and is now feared by Western colleagues to be dead. Vladimir Aleksandrov was a Soviet delegate to SCOPE (the Scientific Committee on Problems of the Environment) and was an active participant in the SCOPE working party on the environmental effects of nuclear warfare.

Reports of last sightings of Aleksandrov vary, but according to one account he expressed his intention of going back to the meeting centre and was never seen again. According to another source, he was last seen being bundled into a car by several men. His personal effects were later found to have gone from his room, but his passport was found in a litter bin.

Former colleagues at the Lawrence Livermore Laboratories in California report frantic messages from Mrs Aleksandrov, who was greatly surprised and concerned at her husband's failure to return.

Aleksandrov was the author of the Soviet computer model using a two-layer model of atmospheric circulation which was presented in Stockholm in November 1983, and which supported the conclusions of Sagan and Ehrlich on the climatic aftermath of a nuclear war. Aleksandrov had allegedly told a Western colleague that he had been told to "get busy" on nuclear winter two months before the Sagan "peer review" meeting at the American Academy of Arts and Sciences in Boston in April 1983.

Aleksandrov had, during the past eighteen months, gradually been replaced as the chief Soviet scientific spokesperson on nuclear winter by Kiril Kondrat'ev, whose papers concentrated on nitrous oxides and trace gas effects, and paid little heed to smoke and dust. This may mean nothing more, however, than that once the computer model was complete, the Hydrometeorological Institute of the Soviet Academy took over the main burden of the nuclear winter campaign.

The silence of Aleksandrov's Western colleagues is difficult to explain. Some, however, seem to have thought that he had defected, and that the car incident was a cover-up. These have expected him to emerge from a safe house in some Western country in due course. But in that case, protest from the Soviet Union about what could well be interpreted as a kidnapping would have been expected, but none has been forthcoming. Nor have there been attempts to brand Aleksandrov

as a defector. One source which claims to be in contact with several Western intelligence services says that it is "not on the cards that the West has him".

If Aleksandrov was repatriated to the Soviet Union by force, as some of his friends now fear, and he was killed either deliberately or in the course of such an attempt, it is not clear what the motive

could have been. One suggestion is that he was feared to be a defection risk. Another is that Aleksandrov had become convinced that the Soviet concern with nuclear winter was merely for public and international opinion and that the Soviet military planners were working on the basis of a "survivable level" of fall-out, and that he intended to voice these views.

Such suggestions, perhaps farfetched, reveal the growing concern about his fate. Hopefully, however, even at this late date, the Soviet Union or some Western government will respond with some explanation and, if possible, the production of Aleksandrov in person.

Vera Rich

Nuclear power

US plans to set industry free

Washington

ATTEMPTS are again being made to revitalize the moribund US nuclear power industry by speeding up the licensing of new plants. Three bills* now before Congress, from the Department of Energy, the Nuclear Regulatory Commission (NRC) and from the industry itself, seek to encourage the use of standard plant designs by giving NRC authority to issue combined construction and operating licences (COLs) at the design stage. At present, NRC must hold a second examination of safety issues before a completed plant can be operated.

The argument is that by forcing all safety issues into a single examination, NRC will give utilities an incentive to perfect complete designs that can be adapted to the requirements of different sites. Construction permits have often been issued for incomplete plans, an approach characterized by the Union of Concerned Scientists (UCS) as "design-as-you-go", resulting in frequent expensive modifications.

There is widespread agreement that the present two-step licensing procedure is inefficient, and that engineering expertise would be better used if there were but a few standard plant designs to be examined. But opponents of the new proposals argue that they fail to encourage standard designs, and that they make it harder to raise serious safety problems once a plant has been built.

Each of the bills recognizes that some kind of pre-operational safety review is necessary before operations can begin, but to prevent determined opponents of a plant from raising questions of safety that have been adequately considered at the design stage, each contains some restriction on the issues that can be raised in a pre-operational review. The NRC bill, for example, says a new issue must be a substantial dispute of fact that cannot be resolved except at a hearing, and that it must either concern non-compliance with a previously-issued COL or a question that

could not previously have been examined. Controversially, the NRC bill also says that for a post-construction modification to be required, it must substantially improve the overall safety of the facility. Overall safety is examined using probabilistic risk assessment, which according to its critics is nothing better than an obfuscatory device that, by being easily manipulable, is used to give spurious authority to safety claims. The NRC bill also raises hackles because it would allow a plant to begin operating before hearings end.

The Department of Energy's bill would make it even harder for safety issues to be introduced retrospectively, as it would allow NRC to make conclusive design approvals that would remain in force for 10 years no matter what information was subsequently discovered; furthermore, it would allow the licensee to deviate from the design in the COL as the licensee saw fit. The industry bill gives intervenors greater latitude to introduce safety issues at a late stage, but requires NRC to perform a central review before incorporating changed requirements. This could mean delays of years.

Opposition to the three bills, voiced more articulately by UCS, focuses on the argument that NRC already has the legal authority to approve standardized plant designs. UCS says it is the fault of the industry that such designs have not been used in the past, because it has sought construction permits on the basis of an examination of very incomplete plans. According to UCS, the depressed state of the industry — no new plants ordered since 1978 — would change if NRC insisted on seeing a complete design before granting construction approval. Industry spokesmen contritely acknowledge that approval of incomplete plans is counter-productive and promise that utilities will submit "essentially complete" plans in future.

Tim Beardsley

*HR 1029 (from the industry) and HR 1447 (from NRC); the Department of Energy bill has not yet formally been introduced in the 99th Congress.

Biotechnology

Variety at *Nature* conference

PLANTS engineered to produce antibodies against viral pathogens, protein frameworks into which various of functional units can be plugged at will and biosensors based on a marriage of immunology and fibre optics were among the more engaging ideas to emerge from *Nature's* "New Technology in Biotechnology" conference at London's Novotel last week.

Clearly the path to commercial reality from an engaging biotechnological idea is long and exceedingly stony, but it is increasingly travelled. Ten years after the discovery of hybridoma technology, John Birch could talk of the production at Celltech of around a kilogram of monoclonal antibody a year, mostly for blood group testing, (see *Nature* 27 June, p. 705) and its sale for, typically, £1,000 a gram.

Clever variations on the basic theme of monoclonal antibodies are already proving their worth at the Molecular Research Council's Laboratory of Medical Biology in Cambridge. Most are the result of engineering the genes for antibodies, replacing an inessential part of the sequence with another gene. The results are hybrid, bifunctional proteins, several of which were described by Michael Neuberger. In one, the substitute gene is for an enzyme used in DNA sequencing. After the hybrid antibody/enzyme is produced in large quantities by standard hybridoma technology, it is very simply and efficiently immunopurified by means of its antibody end; the other end is now supplying the laboratory's considerable demand for the enzyme. On the other side of the coin, a protein that is unable to induce good monoclonal antibodies has been engineered to contain an extra short sequence so that it can be recognized by an existing and excellent monoclonal antibody against the short sequence.

Daniel Thomas of the University of Compiègne foresaw the value of hybrid enzymes in second-generation immobilized enzyme technology. For example, the lifetime of an oxidase that is susceptible to damage by some of the oxygen radicals it produces could be lengthened if the ox-

idase were to be hybridized with a superoxide dismutase, which can consume the radicals. Other important second generation systems would, for example, have built-in systems of co-factor regeneration on electrochemical surfaces or would operate in organic solvents, perhaps to reverse an enzyme reaction or in organic synthesis. More sophisticated protein engineering will involve the subtle redesign of active sites of enzymes, which will remain very much a matter of trial and error until much more is known of the determinants of protein folding, according to Greg Winter of the Medical Research Council Laboratory of Molecular Biology in Cambridge.

R. Brinster

Even without engineering, enzymes and antibodies have many projected uses in biosensors, very few of which have yet progressed from the laboratory to the market place. Michael Flanagan of University College London described prototype optical immunosensors in which the binding of fluorophore-labelled antigen to antibodies immobilized on a surface of the device is measured by means of evanescent light waves of plasmon resonance laser light. For potentiometric devices, enzyme immobilization techniques badly need adapting to suit the surface of microelectronic devices, he said. For amperometric devices, John Higgins of Cranfield Institute of Technology and Leicester Biocentre described current interest both in the organometallic ferrocenes as mediators of electron transfer to electrodes from enzymes bound to them and in a newly discovered class of dehydrogenase enzymes that use pyrroloquinolinequinone as a cofactor in place of the more usual but problematic nicotinamide adenine dinucleotide.

Recombinant DNA technology lags behind that of hybridomas and perhaps even biosensors in its commercialization. But there are products in the offing. Pierre Tiollais of the Pasteur Institute described the advanced state of a hepatitis B vaccine from engineered mammalian cells and Art

J. Schell

Levinson of Genentech claimed that the company's tissue plasminogen activator has been able to dissolve blood clots and restore blood flow through the coronary arteries of some patients in a clinical trial.

For plant breeders, the most immediate gain is likely to be strains that have been engineered to be herbicide resistant, according to Jozeph Schell of Ghent University and the Max Planck Institute for Plant Breeding Research in Köln. Less advanced are attempts to improve potato protein quality and quantity, to transfer light-inducibility to new genes and to engineer cereal crops. And but a glint in Schell's eye is a plan to give tobacco plants the mammalian gene necessary to produce a protective antibody against tobacco mosaic virus. For animal breeders, Ralph Brinster of the University of Pennsylvania offered encouraging news of the general applicability of the introduction of genes into fertilized eggs and the tissue-specific expression of the genes at high levels in the subsequent transgenic animals. One recently learnt fact is that the removal of residual bacterial sequences from a gene construction introduced into the eggs can greatly increase the gene's expression in the tissues of the transgenic animals.

Peter Newmark

● For those who would like a record of the *Nature* conference, cassette tapes are available from: Audio Bass Ltd, 16 Longland Drive, Totteridge, London N20 8HE, UK (Tel: 01-445 6776 or 01-349 4041). Please quote programme number 064-85.

● The correct answers in the exhibition competition were as follows:

1. Tissue culture bottle/Laminar flow hood
2. Eppendorf microfuge
3. Dilon pipetman
4. Scintillation counter
5. Tube sealer
6. Fibre optics

None of the entrants identified all the photographs correctly. Sally Roberts and Pam Jones, both of the Laboratory of Molecular Biophysics at Oxford, got five out of the six right, and in the draw Sally Roberts was selected as the winner of the personal computer. □

P. Tiollais

French education

Higher marks for effort

ONLY 37 per cent of French children attain the coveted *baccalauréat* (*le bac* for short) which guarantees entry to university. But the figure should be 80 per cent by the end of the century, according to the French minister of national education, M. Jean-Pierre Chevènement. Such an increase would raise the number of students in higher education in France to 2 million, four times the figure in Britain, which has a population of the same size.

If all 2 million students were to proceed to higher education, the 80 or so French universities could not cope. At present, with just one million students, as many as two-thirds of entrants leave university after the first year, without a diploma. (Lecturers dub them "ghost students" — some do not even attend courses.) In practice, the ministry of education expects that only a fifth of the extra million French students, who will come through a new form of baccalaureate, *le bac professionnel*, will be seeking places in universities or the French technical colleges, the *Instituts Universitaires de Technologie* (IUT), which are sought after by parents and students because education there usually results in a job.

Others may go to new universities of technology (there is only one at present in France, at Compiègne) or to an "open university", both of which have been promised in recent weeks by the French government. But most of those attaining the new *bac professionnel* are expected to go straight into employment.

The new scheme is designed to loosen up the less academic and employment-oriented French high schools, to make them adapt their education to the real needs and demands of local employers, and to extend the extra 2–3 years of secondary education required for *le bac* (the examination is usually taken at the age of 18) to a wider social group.

The new move must also be seen in its true context as part of the phenomenon of the minister himself. Chevènement is an old-fashioned socialist working in the 1980s. He believes in equality of opportunity: the new *bac* will provide that. He believes in industry: the new *bac* will be tuned to it. But secondary school students will have to work. Chevènement believes in attainment. He also believes in science, as he believes passionately that socialism is equated with knowledge. As President François Mitterrand's first research minister, Chevènement reversed the anti-industry attitudes of most of the French research community, which may be the most substantial achievement of the socialist administration in its four years in power. And now, after a period in political limbo, he seeks to make further lasting marks on France by reshaping the whole education system.

Out have gone the "advanced" liberal attitudes of the 1968 student revolution, whose anti-authoritarian spirit affected schools almost as much as universities, and in has come what the minister calls "republican elitism", basically a renewed respect for an encouragement of academic attainment and for the republican ideals of post-revolutionary France.

"A structured school is more democratic than a lax school", Chevènement wrote recently, discussing the nature of his "elitism". In a lax school, the more confident and middle class pupils rise to the top of the heap. In a structured school, native ability wins through. The proportion of

working class children at universities is still very low, and the minister intends to change that by providing academic and professional opportunities. Hence the new *bac*, which will also have the advantage of helping to train the kind of technicians that new industries need.

Among other important innovations, Chevènement is working on reducing the power of the mathematicians in French schools, which is thought to discourage experimental and observational sciences, in particular biology and geology.

Chevènement has already outlined his ambitions for the universities (see *Nature* 9 May, p.88) but he may not have long to achieve his aims. There will be a general election next year, and the polls suggest that the socialists will be defeated.

Robert Walgate

European computing

Toulouse carries ambitious torch

THE FRENCH proposal for a European computing centre at Toulouse in south-west France, described by a British computer scientist as "a kind of CERN [the European Organisation for Nuclear Research] for computing", has met at least with the approval of Italy. But Britain appears sceptical, while in Toulouse itself, hopes were high for support from West Germany.

That was the position last week over the future of CERFACS, the "Centre Européen de Recherche et de Formation Avancée en Calcul Scientifique", an £18-million-a-year* institute for research and training in numerical analysis whose establishment has been championed for over two years now by a group of Toulouse astrophysicists, aerospace engineers and politicians. According to CERFACS supporters, existing techniques of numerical analysis are out-of-date, having been designed for machines with a single central processing unit. With new computer architectures involving vectorial and, increasingly, parallel processing, where the same or different functions can be performed many times simultaneously, numerical analysis needs to be rethought. CERFACS would do the rethinking, provide training and help apply the techniques to develop areas such as the creation of numerical "wind tunnels" (flight testing by pure hydrodynamical computation).

According to CERFACS supporters, with an eye on the 1986 French budget as it approaches its final month of inter-ministerial bargaining, apart from possible support from Germany and Italy, the Netherlands, Denmark and Switzerland are also ready to join in, provided a second country (other than France) offers support. And in France, while government support is still not guaranteed, there is a chance that CERFACS may be caught up in the political snowball of "Eureka"

(see pages 8 and 9).

But there is some concern in Paris, and even more in London, that CERFACS is too ambitious and costly, and should be prepared to grow "at a natural pace". There are "a lot of traps" in the Toulouse plans for CERFACS to start up in September 1987 with over 100 staff, rising to nearly 200 by 1991, it is said in Paris. In London there is a feeling that the centre would not offer "value for money".

Professor Jean Yoccoz, the director of the French nuclear and particle physics institute IN₂P₃, however, says "there are always pluses and minuses" and that "the best of CERFACS" is its plan to mix industrial and fundamental research on one site, as well as training. And Toulouse, with its aerospace and robotics industry, "is a good place for that, at least for France".

A leading British computer scientist, however, is less impressed. He feels the emphasis on new numerical and software techniques for use with vectorial supercomputers is "very esoteric" and "not leading edge computing science".

In Toulouse, however, these criticisms have been met with "surprise". CERFACS is prepared to deal with whatever computer technology is in the forefront, be it a vectorial Cray 2, or the German multiprocessor Suprenum, or a machine still on the drawing board. Far from being esoteric, CERFACS — or something like it — would be essential to the proper use in Europe of these new machines, it is claimed in Toulouse and whatever equipment was provided would moreover be networked to users throughout Europe. "We aim to respond to user needs", a spokesman says. And although the planned rate of development of CERFACS is indeed ambitious, Europe cannot afford to wait to be pre-empted in yet another area by the United States and Japan.

Robert Walgate

Deep-sea drilling

Britain squeezed onto margins

Washington

STRAINS are beginning to show over Britain's continued inability to find the \$2.5 million membership fee needed to join the Ocean Drilling Program (ODP). British scientists have been removed from all planning and advisory committees of the programme, and according to Robert Kidd, manager of scientific operations of the research vessel *Joides Resolution*, British scientists are unlikely to be invited to participate in future cruises.

Britain at present enjoys observer status in ODP, which permits it only to send an observer to meetings of the executive committee of Joint Oceanographic Institutions Deep Earth Sampling (JOIDES). Japan, which also has observer status, recently signed a memorandum of understanding with the United States saying that it will join the programme as a full member at the start of October this year; no such guarantee has yet been made by Britain. As a result, the only British scientist on the current cruise of *Joides Resolution* in the Norwegian Sea, Lindsay Parsons of the Institute of Oceanographic Sciences, is likely to be the last until Britain rejoins, unless there is a cruise in British territorial waters.

Planners at ODP find themselves in a political bind: although they want to invite individual British scientists because of their expertise in particular fields, it is felt that it would be unwise to send the British government a signal that its best scientists will be able to participate in ODP whether or not Britain becomes a member. The assistant programme director of ODP at the US National Science Foundation, Alexander Sutherland, says JOIDES has been "pretty adamant" that British scientists should not be offered guaranteed places, out of fairness to participating countries. Dr Parsons' participation in the current cruise, leg 104, was arranged before the JOIDES committee forbade guaranteed places for British scientists, and was supported (despite misgivings in some quarters) by the two co-chief scientists on the cruise, Olav Eldholm of the University of Oslo and Jorn Thiede of the University of Kiel.

Britain's difficulties in finding the necessary money has particularly annoyed Canada, which has paid despite having a much smaller gross national product. Although the European Science Foundation and Australia may join ODP as a consortium, JOIDES has ruled out the possibility of Britain joining as part of a consortium.

Britain's Natural Environment Research Council still hopes to be able to raise the necessary funds in time, although many people in the United States seem resigned to the fact that Britain will not be a member next year, at least. One political

factor that may yet carry the day in Britain, however, is a planned cruise in the Weddell Sea: a scientific interest and

presence in Antarctica would undoubtedly bolster British negotiating positions when the Antarctic Treaty comes up for renegotiation at the end of the decade. Only by being in at the planning stages will Britain be able to influence the shape of the cruise.

Tim Beardsley

Auto emissions

Europe agrees at last

Brussels

AFTER an all-night session, environment ministers of the European Economic Community (EEC) came to the close of their meeting in Luxembourg on 28 June just in time for breakfast with agreement on new tougher European exhaust emission controls, the first of which will be applicable from 1988.

The deadlock over this controversial issue, which has kept the environment ministers busy over one aspect or another for two years, was overcome by a decision not to follow the US example, despite pressure from West Germany, to quantify the exhaust emission limit for nitrogen oxides (NOX) on their own for cars in the intermediate range of 1.4 to 2.0 litres.

The combined figure for nitrogen oxides and hydrocarbons (HC) has been common practice until now in the regular modifications made to the 1970 EEC directive on exhaust emissions, and gives motor manufacturers room for manoeuvre within a range of engineering options. In getting to grips with emissions, one of the problems in engine design is that modifications to the combustion process aimed at reducing, for example, hydrocarbon emissions increase the production of NOX and *vice versa*.

The limit finally agreed — 8 gram/test for HC and NOX together, the European Commission's proposal — falls half-way between what West Germany wanted on the one hand and what the British were prepared originally to accept on the other.

For the United Kingdom, the difficulty lay in accepting a figure that it might be impossible to obtain using lean-burn single-point ignition, under development in the United Kingdom. Furthermore, the use of this technology (lean-burn plus oxidation catalyst) had been part of the agreement hammered out by environment ministers at their previous meeting in March. As it turned out, Mr William Waldegrave, Under Secretary of State at the UK Department of the Environment, agreed on his own responsibility to the

figure pending a government decision in London. No hitches are expected.

This spirit of European compromise has meant less of a warm welcome from environmentalists in West Germany for their interior minister Friedrich Zimmermann, for whom coherence in the Community's external market, at the end of the day, outweighed tough political pressure on a national level.

Ministers also accepted a number of other ancillary points, said to have been initially proposed by French environment minister Huguette Bouchardeau, which aim at further reducing exhaust pollution (and tension between the member states):

- That small cars (under 1.4 litre) would have to conform earlier to stricter standards, bringing them in line with US environmental equivalent effects, by 1992 for new models and 1993 for all new cars.
- That the United Kingdom and France would agree to drop complaints made to the European Commission against the national fiscal incentives for "clean cars" announced by West Germany at a time when European legislation on the subject was being prepared (illegal under Community law).
- That the Commission should propose legislation in the next three months to limit emissions from lorries, and in particular on diesel particulates (see *Nature*, 311, 401; 1984). Ministers also laid down new standards for diesel engines with a capacity of 2 litres and over. While, in the past, limits for diesel engines have had the advantage of a 25 per cent waiver in their favour, they will in the future have to comply with the same new limits established for the intermediate range of conventional car engines.

● That the Commission should make proposals on speed limits and on a regular monitoring system on vehicle compliance, possibly based on the tough system applied in Belgium.

In addition, the Commission itself may decide to propose further measures.

Anna Lubinska

	Emission standards		Deadline (1 October)	
	CO	HC + NOX	New models	New cars
Cars over 2 litres	25	6.5 (3.5 NOX)	1988	1989
Cars of 1.4-2 litres	30	8.0	1991	1993
Cars below 1.4 litres	45	15.0 (6.0 NOX)	1990	1991

(Stage 1)

(Stage 2 to be agreed in 1987 with implementation by 1992-93)

Japanese education

Council's criticisms start row

Tokyo

JAPAN's special Council on Education, set up to prepare a blueprint for a massive reform of the education system, delivered its first set of recommendations last week to a chorus of complaints and disapproval.

It is only ten months since the council, with its 25 members all personally picked by Prime Minister Yasuhiro Nakasone, began its activities, so it is perhaps not surprising that it has been unable to reconcile all the fiercely held views on this emotive subject. But the report is more of a philosophical declaration than a practical recipe for reform.

The report castigates the present education system in terms which, if they had been written by a foreigner, would probably have given rise to complaints of anti-Japanese prejudice. The system is accused of producing "too many stereotyped persons without strong individuality" who are not "able to think and judge on their own" because they have been taught only to "memorize information and facts". "Bullying in school, pupils' absenteeism, violence at school and juvenile delinquency" are also described as "grave" and as products of the present system, although Japanese schools are havens of peace compared with those in the West.

To remedy this situation, strong emphasis is placed on the fostering of "individuality". But although this Western notion is repeatedly endorsed, far more column inches of the report are given over to the need to reinforce distinctively Japanese values: children "must love Japan", maintain "a deep understanding and love of Japanese culture" and have "identity as Japanese". These values were, of course, inculcated in the education system that existed before the Second World War, which, indeed, comes in for some oblique praise, while post-war education is criticized for putting "a disproportionate emphasis on rights instead of duties". To the Socialist and Communist parties (the second and fourth largest parties in the Diet) such statements are like a red rag to a bull and they have attacked the report furiously, pointing out the difficulties in a system which is meant to teach people to "think independently" while "fostering Japanese who will inherit the traditional culture".

Philosophical contradictions aside, the report is firm in identifying the real villain behind educational woes: a society that gives too much preference to graduates from leading universities. Because top corporations and ministries recruit from just a few universities, the whole educational system has become oriented towards success in the university entrance examination "hell". In that examination, all that counts is overall score in multiple choice questions; the higher one's score

the better the university (or faculty) one can enter, regardless of vocation and aptitude. The report makes an appeal for a change in attitudes away from a society oriented towards "academic record", but clearly such changes are beyond its power to effect.

A more direct attack is made on the university entrance examination. A new first-stage unitary examination is proposed for use by all universities, public and private, to replace that now used only by public universities. The burden on students, who usually try more than one kind of examination, would thus be eased.

To try to ease competition further down the system, new kinds of schools are proposed that will fuse junior and senior

high-school. Entrance examinations for high-schools have recently become almost as fraught as the university entrance examinations themselves. It is suggested that some such schools work on a credit system for high-school graduation rather than rely on intensive examinations to increase the flexibility of the system.

The Council on Education will now soldier on for a further two years, trying to build on this somewhat shaky start. The Prime Minister is giving full backing to the council, and a cabinet-level group is expected to be formed to put its weight behind its recommendations. So far, however, teachers are opposed, the Japan Teachers Union having sworn to fight the reforms "to the end" a few days before the report was even published. The teachers' main concern is to get average class sizes down to 35 from present levels which are closer to 40 pupils.

Alun Anderson

Soviet Antarctica

Trapped vessel in good shape

THE Soviet research vessel *Mikhail Somov*, which has been trapped in the Antarctic pack-ice for more than three months, could eventually drift to safety along a route mapped by a previous expedition aboard the same vessel. Accord-

ing to Candidate of Sciences Al'bert A. Romanov, of the Arctic and Antarctic Research in Leningrad, the ship's present course virtually coincides with that of an iceberg, mapped by radio beacon as part of a Franco-Soviet experiment in 1980-82. The tagged berg drifted on a semi-circular course for more than 3,400 nautical miles before emerging into the warm waters of the Pacific.

The planners of the 30th Soviet Antarctic expedition, of which *Mikhail Somov* is the flagship, do not, however, intend to leave the crew and research personnel trapped for so long. Some 77 people have already been flown out by helicopter, leaving 53 on board for essential ship maintenance and observations of conditions in this previously unexplored sector of the Antarctic. (Conditions are severe, with winds of 17 metres per second, temperatures of -25°C , poor visibility, snowstorms and fog.) Meanwhile, a special taskforce has been established under the deputy head of the state committee for

hydrometeorology and environmental control to "ensure a rapid solution" of the "*Somov* problem". The icebreaker *Vladivostok* of the Far Eastern Shipping Line has been sent south, and is expected to approach *Mikhail Somov* at the beginning of July.

Because *Mikhail Somov*, with its now reduced complement, is well provisioned for another 10 months, evacuation plans are, so far, of a contingency nature only. A specially adapted Mi-8 helicopter is on board the *Vladivostok* to evacuate the *Somov* personnel in case of emergency.

For the moment, *Vladivostok's* chief role will be to try to break a channel through to the trapped vessel and, if necessary, tow it out. If *Somov* could break through into the relatively young ice of the Ross Sea, the most difficult part of the mission would be over. Meanwhile, scientists are continuing their work aboard the trapped vessel, including, presumably, the seismo-acoustic probing of the sea-bed that was a major feature of the ship's original programme. It is unfortunate that Soviet plans to have all seven permanent Antarctic stations equipped with Inmarsat receiving and transmitting equipment have not yet been implemented. So far only one such station, the Molodezhnaya observatory in Enderby Land, is so equipped, while the two nearest to the trapped ship, Russkaya and Leningradskaya, are linked to Leningrad only by shortwave radio.

Vera Rich

Correction

There was an error in last week's story about laser fusion (*Nature* 27 June, p.706): the current budget for inertial confinement fusion is about \$140 million; the administration proposed halving this sum in the fiscal year 1986.

Eureka

Brussels hope after Milan chaos

Brussels

WITH the key issue of institutional reform referred, reluctantly by some, to an inter-governmental conference to take place later this year, the approval by heads of government of the European Economic Community (EEC) of the idea to give the Community a new technological dimension may be considered as, at least, one positive result at the end of the two-day summit in Milan. But a series of questions still remain unanswered.

EEC heads agreed that technology in the Community should be strengthened. Thus they agreed that there should be a close link between technological development and the effort to unify the internal market, that technological effort should be closely tied to common policies as on trade policy, that duplication of national efforts should be reduced and money pooled.

The Milan summit also endorsed a Community report on the subject but the heads of government gave no clues as to the form research collaboration would take and who would coordinate it.

Questions of financial support and structure will be considered at an *ad hoc* meeting on European technology by EEC research ministers and "other qualified representatives of governments" (which may imply industrial participation). Government heads asked the French (perhaps not insignificantly) to convene a meeting in Paris, probably on 17 July. These "technology assizes" will also include the new (from 1986) EEC members Spain and Portugal, as well as non-EEC countries Austria, Sweden, Switzerland and Norway to whom participation in projects will be open and who have expressed an interest. At Milan, two proposals were put forward, the Eureka project in which countries and companies may collaborate unilaterally or in groups according to the dictates of interest and investment capacity, and the Commission proposal which would like to see the Eureka project as part of a flexible structure coordinated on a Community level, with projects operating on the lines of the Joint European Torus at Culham in the United Kingdom.

The Commission proposal has the advantage of being able to fall back on existing structures, and it has the support of the smaller member states which need to share the financial burden of technological research investment. EEC research commissioner Karl-Heinz Narjes has suggested the creation of a corridor in the research budget as well as increasing the share of the budget itself.

The other possibility is that Eureka might develop separately, out of reach of Community control (which would please President Mitterrand) but which would be overseen by an intergovernmental agency

which would at the same time keep an eye on the Community programme and would thus coordinate the two. A possible candidate for the job is Viscount Etienne Davignon, ex-EEC research and industry commissioner and father of the much quoted ESPRIT programme which launched cooperation between European industry and universities. In this second case the ten Community countries would be treated as just another member state in

Eureka

Companies ready to bid for funds

WHILE European heads of state have been debating whether and how to go ahead with Eureka, the French proposal for a joint European technology programme, electronics companies in Europe have been defining projects that their political masters might support. Last week GEC (United Kingdom), Siemens (West Germany), Philips (The Netherlands) and Thompson (France) announced that they have already set up a study group to make joint proposals to Eureka, while the Norwegian computer company Norsk Data and the French defence, space and electronics group, Matra, announced the development of a super-mini-computer, a "Crayette" (for scientific use) under the Eureka banner.

These are some of the first concrete developments to flow from the Eureka idea originally proposed by President Mitterrand of France to provide Europe with an alternative to participation in the US star wars programme. The speed with which they have been put in train would seem to indicate that Eureka has touched a receptive nerve.

According to British GEC, experience of the European Commission's ESPRIT programme for pre-competitive research in information technology, while positive, has indicated the need for more market-oriented cooperation in real product development, which might be stimulated by Eureka. ESPRIT itself has "barely started", but has shown that an "unbiased" organization like the Commission can catalyse cooperation, spanning national frontiers.

A further factor is money. While nothing has been agreed, French sources have suggested that France alone would be prepared to contribute an initial £100 million to Eureka. Development costs in electronics seem to be increasing exponentially, according to Philips (Eindhoven) directors, so that the potential availability of public pots of gold is stimulating. International cooperation in development would also ease the burden.

What products are in the offing? Derek

participating in Eureka projects.

Conceding that Eureka should develop separately would allow at least some member states to get going on technological research while the institutional debate in the EEC continues. For even if the Commission maintains that the proposal is based on existing operational rules, bringing about a "qualitative technological leap forward" will require, as Jacques Delors, president of the European Commission, insisted before the Milan summit, changes to inject dynamism into functioning of community institutions and encourage the creation of an internal market.

Anna Lubinska

Roberts, technical director of GEC, appears to have in mind new transportation systems and traffic control systems, while pan-European cellular radio networks are also in the air. The French have also been pushing for the development of a large European super-computer to rival the Cray machines.

Meanwhile, Norsk Data, which first made its name by supplying the computer control systems for the super proton synchrotron at CERN, and Matra are working together on a more immediate project, to develop not a European Cray, but something that might be described as a "Crayette".

The two companies have already been cooperating on the development of a 32-bit mini-computer to supplant Digital Equipment's ubiquitous VAX and, says Matra, they have identified a market gap for desk-top vectorial machines. These, like the Cray, offer a degree of parallel processing, essentially performing instant matrix multiplications on columns of numbers ("vectors") many elements long. Such computers are proving essential in number-crunching operations as in quantum chemistry, atmospheric modelling and seismology, but they are at present very expensive, ranging from £1 million to £10 million.

Norsk Data and Matra, however, hope to come on the market (with the help of Eureka) in two years with a vectorial machine of some "hundreds of millions of operations per second" at a price of only £100,000 to £1 million, compared with the current price of a VAX of around £60,000. Matra is aiming at the market for 32-bit minis in 3-4 years time.

One Cambridge quantum chemist said last week that "there's no doubt that this is the way it'll go" and that the Matra/Norsk Data proposal sounded "extremely competitive". The present cost of vectorial computing is a real hindrance to its development, he said. Companies such as Convex of the United States would be in competition with the European group, however.

Robert Walgate

Bioethics

US Congress tries again

Washington

THE US Congress is trying to fill the gap left by the 1982 demise of the President's Commission on Bioethics. Last year's attempt failed when President Reagan vetoed the National Institutes of Health (NIH) authorization act, which included provisions for a panel to monitor human genetic engineering, protection of human research subjects and other issues in medical ethics.

Last month, the House of Representatives again passed the NIH bill proposed by Representative Henry Waxman (Democrat, California), largely unchanged from last year's version. A similar bill is pending in the Senate. But its fate must be uncertain. Both House and Senate bills retain the features its president found objectionable last year, in particular the detailed specification of each NIH institute's research mission labelled, in the veto message, as "micromanagement" by Congress. Both

bills also call for two new NIH institutes, one for arthritis and one for nursing. NIH has long opposed the creation of new institutes, which it says add to its administrative costs without augmenting or improving the research.

Even if there is a veto, the bioethics panel may survive. Senator Albert Gore (Democrat, Tennessee), a key supporter of the concept when he was in the House, has filed a separate measure much along the lines of the section of the House and Senate bills dealing with the panel. A bipartisan board would appoint a committee of biomedical researchers, physicians, ethicists and laymen to carry out studies of ethical problems in biomedicine. The committee would have no regulatory function and would operate as an agency of the legislative branch, akin to the Office of Technology Assessment and the General Accounting Office. There is a strong feeling among even supporters of human gene therapy that a high-level but nonregulatory panel would be the best way to evolve policy on its new medical technologies while disarming the more extremist critics. A less-favoured alternative is an expansion of NIH's Recombinant DNA Advisory Committee (RAC) which has begun to draft guidelines for human gene therapy experiments. But RAC, as part of an executive branch agency, also lacks the formal independence that many would like for an ethics panel.

Another role of the ethics panel would be to straighten out the muddle over fetal research. Under current rules, NIH may not support research posing "greater than minimal" or "unknown" risks to a fetus. Although the Secretary of Health and Human Services (HHS) is allowed to grant a waiver if an experiment has passed the scrutiny of the local Institutional Review Board, the advisory council of the relevant NIH institute and a specially empanelled Ethical Advisory Board, the Secretary of HHS has never been willing to appoint an Ethical Advisory Board. In effect, there is a total moratorium.

Under the House and Senate NIH bills, the ethics panel would be asked to study the question of experiments involving unknown or greater than minimal risks. Waxman said he had reluctantly agreed to go along with the Senate's insistence on a 3-year moratorium even on waivers in the hope that this would allow time while "tempers cool and rhetoric dies down". He noted, for example, that a study on the dangers of vaccinating pregnant women against rubella, which was carried out in 1969, before the current rules became effective, would probably now require a waiver. In that study, women planning to have therapeutic abortions were vaccinated, after the abortions took place

11 to 30 days later, fetal tissue was examined to determine if the vaccine virus was able to cross the placenta and infect the fetus. The answer, contrary to expectations from animal studies, was yes; and physicians were ordered not to administer the vaccine to pregnant women.

As a practical matter, however, the 3-year moratorium will not affect research, and Waxman said he hoped that after a "full and even-handed" review by the ethics panel, the Secretary of HHS would "proceed with the responsibilities to pursue research ethically and without regard to purely political pressures".

Stephen Budiansky

Ethics in science

Washington

ONE of tenets of the scientific method is that researchers are supposed to share their data with others who wish to verify or expand on their work. That that apparently does not always happen is the unstated but clear implication of a new report from the National Academy of Sciences* urging the adoption of guidelines by grant-making agencies and scientific journals that will normally require data-sharing.

The report recites the usual reasons for sharing data: encouraging open scientific inquiry; allowing for verification, refutation or refinement of original results; bringing multiple perspectives to bear; encouraging interdisciplinary use of data; and detecting the rare cases of fraud.

But, the report notes, researchers may be reluctant to hand over their data to other researchers for various reasons.

The report recommends that researchers make their data available by the time of publication of the initial major results: "the practice of withholding data until all possible analyses are exhausted is unnecessarily restrictive and too self-serving to advance science", it said. Those who request data should bear any incremental costs, however.

Government funding agencies, the report says, should require applicants to guarantee data-sharing or to justify explicitly, in their grant proposals, why they should be exempt from the requirement. The National Science Foundation (NSF), for example, already requires that "data banks or software" produced with NSF grant funds be made available to others; the report notes, however, that the policy could be strengthened.

Finally, the report recommends that scientific journals should require authors to provide peer reviewers with access to their original data and "strongly encourage" them to provide similar access to others, and should give more space to reports of secondary analyses and replications to encourage the process.

Stephen Budiansky

*Sharing Research Data, Committee on National Statistics, National Academy Press, 1985

Paris scents triumph

Paris

IN France, the feeling over Saturday's summit debacle over the European Community's Treaty of Rome appears to be one of sweet revenge over that De Gaulle of an Englishwoman, Mrs Margaret Thatcher, and for the years of confrontation over the British budget in Brussels. But the sweetness will certainly turn sour if the result is to damage the French-inspired Eureka project for European technology.

So far, however, all seems well. The summit has produced an agreement to hold here in Paris in the second half of this month a "technology conference" of European foreign and research ministers which should, at last, result in the definition of exactly what Eureka will be, who will run it and who is prepared to pay. But the fear among those closest to Eureka in Paris may be that the conference will be compromised by the arguments among their political masters in Europe over other issues.

The French sources were at pains on Monday to distance Eureka from the battle. "Mrs Thatcher showed herself quite constructive on technology", a French research minister spokesman said, and the split over veto rights and the Treaty of Rome was "quite another question".

The apparent conflict in Milan between François Mitterrand and the president of the European Commission, Jacques Delors, was also being played down in Paris this week. The view here is that the European Commission can be "closely involved" and that "Eureka is not in conflict with the Commission". The communiqué from Milan "took note of and endorsed" Delors' plan. Robert Walgate

A capital Universe?

SIR — On one side of the Atlantic, authors and editors continue to use the word universe, whereas on the other they have changed over to the word Universe. Last year, while hastily proofreading an article written for a British journal, I failed to notice that the copy editor had everywhere altered the common noun universe into the proper noun Universe. When the article was published, I realized too late that this apparently harmless alteration had changed in a significant way my intended meaning. By no stretch of the imagination can a universe become the Universe.

Elsewhere¹ I have pointed out that current knowledge and usage assign different meanings to universe and Universe. The Universe means everything, including ourselves, and no doubt our descendants in the distant future will still be trying to understand the ultimate nature of reality. Nobody knows what is the Universe. Illogically, as a proper noun in common use, Universe denotes nothing more than a model of the Universe. When editors delete "universe", they should substitute not "Universe," but "model of the Universe".

The more modest and flexible word universe usually denotes "a model of the Universe". By using universe we avoid the meaningless Universe and the terminological rigmarole of model of the Universe. Every society has its universe or model of the Universe. We in the twentieth century have our physical universe, which is still a long way from being the Universe. We debate the rival merits of big-bang and steady-state universes, and under the rubric early universe discuss the virtues of the inflationary universe. (What a mess the last sentence becomes if Universe is substituted for universe!) Our descendants, though part of the same Universe, will live in different universes. In the history of cosmology we study the rise and fall of universes, or cosmic belief-systems, or models of the Universe, but not of Universes.

Indiscriminate use of Universe confuses the real thing with a model. As a result we forget that we have precious little knowledge of the true nature of the Universe. Like our forebears in past millennia, we tend to think that the end of the search for all knowledge looms in sight. Most people in the past, in the Middle Ages for example, were convinced that they had discovered the real thing. People with different models often finished up at the stake.

There exists only one Earth, and similarly only one Universe. But the difference is vast in more senses than one. With the first we know more or less what we are talking about, but with the second we have no idea. The curious words earth and Universe found in many journals and books look most odd. Logic dictates that we capitalize proper nouns such as Earth,

Sun, Solar System, Galaxy, Local Group, and leave it at that.

Imunovir

SIR — Replying to my letter¹ criticizing the UK campaign for the launching of isoprinosine (or Imunovir) as an effective anti-herpes treatment, Helen J. Wright made, on behalf of the laboratory commercializing the drug, numerous assertions and insinuations². I feel obliged to comment very briefly on some of them; the readers of *Nature* will have no difficulty in seeing most of the contradictions and the reasons for this defence.

To call W.H. Wickett's drugstore book³ an objective "independent text" on herpes does not correspond to reality. The author conducted, on behalf of the manufacturers (Newport Pharmaceuticals), a non-controlled clinical trial on herpes patients, and he reported his results in this book. If the name of the "test drug" is not mentioned until p.217, and this on the express request of the manufacturers, it is mentioned 12 times in the references between pages 218 and 225. The tantalized reader will have no difficulty in discovering the substance producing the wonderful results. But there is something more puzzling: Wickett apparently published his results only in this book and reported them at a couple of scientific meetings. Why do such extraordinary results, and those obtained by others using the same drug and cited by H. Wright, remain at the stage of meeting abstracts, which even a computer survey fails to pick up?

Bona fide readers who saw the various assertions concerning the drug are still wondering what the drug really does for herpes patients, whether it cures the "bouts"^{2,3} or diminishes to "nearly zero" the frequency of the attacks⁴. If this were the case, the number of patients should indeed decrease.

I am not surprised that articles such as those in the *Financial Times* and the *Sunday Times* promising a miraculous cure for diseases of great psychological impact — even if the titles of articles are written, as H. Wright suggests, by "irresponsible sub-editors" — are found "well balanced" by those whose main concern is the sale of the drug. I maintain that articles written for the lay public should be underplayed rather than exploit the spectacular. Readers of lay publications do not usually read journals such as *Nature*, where statements are made with extreme care, despite the fact that, or perhaps because, the readers

take everything with several pinches of salt.

This is the case of C. Wenz's article where the author cautions, because of the placebo effect, against drawing hasty conclusions in assessing the efficacy of Imunovir "until more clinical trials have been completed"⁴.

H.J. Wright has confirmed my belief that only those with vested interests would reject my criticisms and the idea of exercising self-censorship against aggressive publicity. I am certain that most will refrain from such practices and I also hope that the lay media will adopt a more restrictive policy in printing news related to health matters.

Fuels from the farm

SIR — There seems to be an error in Anna Lubinska's article (*Nature* 4 April, p.395). It is stated that 8 million tonnes of cereal surpluses could produce 2 million tonnes of ethanol and that 1 hectare of land can produce 4 tonnes of ethanol. This would mean that 1 hectare of land produces 16 tonnes of cereal grain, but that is surely not the case. A good average yield through the countries of the European Communities is nearer half this figure. It should be borne in mind that the vagaries of the cereal intervention system ensure that it is the less efficient farmer who actually produces the surplus. These farmers are more likely to produce 4 tonnes per hectare of low quality cereals. The immense complications of agricultural production should be borne in mind when calculating potential hydrocarbon energy production by farms.

Nullius in verba

SIR — It was good to have the exact meaning of the Royal Society's *Nullius in verba* explained by the president (see *Nature* 23 May, p.272). In all fairness to young scientists, however, he should have urged caution in taking the society's motto as a rule to walk by. For those who reveal too early their realization, which will come soon enough if they are independent thinkers, that many authorities of the day are emperors with very threadbare clothes, the going is likely to be rough.

ZIDASTM

cuts the cost of quantitative microscopy down to size.

Now, for under \$7,500, the Zeiss Interactive Digital Analysis System... ZIDAS...with Printer, Standard Microscope, and Tracing Attachment.

VERSATILE

- ☐ 18 geometric and morphometric measurement functions
- ☐ Statistics, stereology, distribution histograms
- ☐ ZIDAS will operate:
 - As stand-alone system
 - With practically any computer
 - With practically any serial or parallel printer
 - With display terminals

BUILT-IN SOFTWARE

- ☐ Internal auto-diagnostic and test programs
- ☐ All programs permanently resident in EPROM
- ☐ Up to 5 user-defined programs can be stored in memory at one time
- ☐ 9 separate registers

SIMPLE TO OPERATE

- ☐ Clear, easy-to-understand menufield
- ☐ Images are traced with stylus or cursor
- ☐ Direct microscopic observation, prints, photos, drawings
- ☐ Tracing speeds up to 100mm/second
- ☐ Tablet resolution better than 0.1 mm

HIGHEST QUALITY MICROSCOPE

- ☐ Unmatched for versatility
- ☐ Compact, strong, simple
- ☐ Classic design, superb optics, precision mechanics
- ☐ 131 objectives, host of accessories
- ☐ Usable in every known technique in transmitted- and reflected-light microscopy

One Zeiss Drive
Thornwood, NY 10594
(914) 747-1800

nature

WHAT IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

**OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL
SAN FRANCISCO, CALIFORNIA**

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.

Full 3-day registration fee: \$375.00

Pay only \$325.00 if you register before July 31.

LOCATION

The Sheraton-Palace Hotel located at 639 Market Street

is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling: 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: \$95. Doubles: \$105 and \$115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

**YOUR REGISTRATION FEE
COULD BE TAX DEDUCTIBLE**

CONFERENCE DINNER

Our gala Conference dinner will be held Tuesday, October 8, in the historic, glass-domed Garden Court. To insure seating, please include your dinner ticket requirements and payment of \$29.50 per person with your registration.

EXHIBITS

A major exhibition of scientific products and services will be held in conjunction with the Conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

SYSTEMS

Speakers

F. Bloom
(Research Institute
of Scripps Clinic)

J. Gerhart
(U. of California
at Berkeley)

C. Nüsslein-Volhard
(Tübingen)

C. Goodman
(Stanford)

H.R. Horvitz
(MIT)

Topics

Vertebrate neural
systems

Early development—
Xenopus

Early development—
Drosophila

Development of
invertebrate
neural systems

Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers

M. Davis
(Stanford)

U. Storb
(U. of Washington
at Seattle)

J.M. Bishop
(U. of California
at San Francisco)

M. Ptashne
(Harvard)

I. Herskowitz
(U. of California
at San Francisco)

E. Jaworski
Monsanto

Topics

T-cell
receptors
B cells

Oncogenes

Regulatory
proteins
Yeast
development

Plant
transformation

DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers

R. Palmiter
(U. of Washington
at Seattle)

D. Hogness
(Stanford)

W. McGinnis
(Yale)

T. Friedmann
(U. of California
at San Diego)

Topics

Transgenic mice

Drosophila
homoeotic genes

Mammalian
homoeotic genes

Human therapy

*Additional speakers will also appear on the program.

**SAVE \$50
IF YOU
REGISTER
BEFORE
JULY 31!**

REGISTRATION FORM

To register for NATURE UPDATE IN MOLECULAR BIOLOGY 1985, mail this form with your payment to: NATURE PUBLISHING COMPANY, 65 Bleecker Street, New York, NY 10012

(Photocopy this form for additional applications.)

OLYMPUS

Revolutionary New Automatic Microscope

It is not often that something revolutionary is developed in the world of microscopes. But the new Vanox Microscope from Olympus is just that. A built-in computer sets the illumination to suit the objective selected. The microscope has Autofocus on the low power objective. The majority of controls are motor

driven and controlled by a simple panel at the side of the microscope. All this and a choice of three cameras in one microscope, with a fully automatic exposure control and spot metering makes the new Vanox something you need to see to believe. For more information on Olympus microscopes ask Gallenkamp.

Uniting mechanics and statistics

An adventurous scheme which seeks to incorporate thermodynamics into the quantum laws of motion may end arguments about the arrow of time — but only if it works.

THE logical relationship between the laws of mechanics and those of thermodynamics deserves more attention than it usually receives. Thermodynamics and statistical mechanics are ways of describing the behaviour of macroscopic systems made from components whose behaviour is determined by the laws of mechanics, classically those of Newton (as amended), but otherwise the equations of motion of quantum mechanics. Where the first law of thermodynamics is concerned, there is no difficulty. In both classical and quantum mechanics, total energy is a constant of the motion and is thus always conserved, at least in a closed system.

The difficulty arises chiefly with the second law of thermodynamics, and not only because there is such a variety of ways in which this principle can be defined. But now a group of three theoreticians has put forward an intriguing way in which the laws of quantum mechanics may be modified so as to incorporate the second law from what appears to be the outset (Beretta, C. P., Gyptopoulos, E. P. & Park, J. L., *Il Nuovo Cimento B* 87, 77–97; 1985). Whether the modification proposed is sufficient, only time will tell, but the objective seems well worth the trouble Beretta *et al.* have taken.

The difficulty is well illustrated by the way in which some kind of correspondence is established between the mechanical behaviour of a system and its thermodynamic properties. For more than a century, people have been brooding on the paradox that while the laws of classical (and, for that matter, quantum) mechanics are symmetrical with respect to time inversion, the second law selects from all possible trajectories of motion only those corresponding to a continual increase of the entropy. The arrow of time is conjured like a rabbit from a hat.

The definition of entropy in terms of the mechanical properties of the constituents of a system is similarly clouded. The classical model is Boltzmann's H -theorem (1872), which shows that the rate of change with time of a certain mathematical construct from the probability distribution of single particles in phase space will always be zero or negative. So Boltzmann argued, his quantity H is admirably suited to be the negative of what is known in thermodynamics as entropy. This is argument by analogy, but none the worse for that — if it works.

Since Boltzmann's time, there has

accumulated a rich literature on the implied paradox of the conflict between the irreversibility of macroscopic processes and the reversibility (in time) of the laws of mechanics and thus of microscopic processes. Indeed, the argument was begun by Loschmidt in 1876, but now even elementary text-books of thermodynamics reckon to give some kind of account of it.

The standard explanation is that the apparent paradox is not a paradox at all, but a confusion about timescales. Any measure of entropy, that derived from Boltzmann's H or otherwise, will fluctuate (and so decrease as well as increase on a short timescale), which is not inconsistent with the notion that the average value of the entropy should increase steadily over long periods of time (or remain unchanged when the system is in equilibrium).

Much the same is said of the recurrence paradox, based on the observation due to Poincaré that the point in phase space (momentum as well as position) representing the state of a classical system will return to more or less the same place after a sufficient length of time. On the face of things, that means that non-equilibrium states of a system will repeatedly recur. The standard resolution of that paradox is the observation that, for any realistic system, the interval of time between recurrences will be huge, much greater than, say, the age of the Universe. Again there is nothing wrong with these arguments, but they are far from being rigorous.

So why not take the bull by the horns, and build irreversibility into the laws of mechanics? That is the point from which Beretta *et al.* start. Properly, they acknowledge that they are not the first to tread this path. They work with quantum statistical mechanics, where the formalism is easier. They start from the equation of motion for the operator representing the state of a physical system, say m , which is, in operator language, $dm/dt = -i/\hbar [H, m]$, where t is time, H the Hamiltonian operator of the system and i and $\hbar$ the square root of minus one and Planck's constant (divided by 2π) respectively. The quantity in square brackets is the commutator of its two components, $mH - Hm$.

The natural way to proceed is to assume that this equation is modified in such a way that the right-hand side is some other function of the state operator m than in the standard form. The objective is to find a form of the function which is compatible

both with what is known of the evolution of thermodynamic systems and, perhaps more important, the dynamics of real microscopic systems. Beretta *et al.* have convinced themselves that the function they are seeking cannot be a linear function of m . What they propose is the addition to the right-hand side of the quantum equation of motion of a particular function of m which, by including both the square root and the logarithm of the state operator of the system, is non-linear enough to satisfy anybody's taste.

Almost magically, the system has some of the obviously necessary properties. For example, for a system in a pure quantum state, say that represented by a solution of Schrödinger's equation, the extra terms vanish and the simple form of the equation of motion applies. Similarly, constants of the motion in the new system are also constants of the motion determined by the simpler equation of motion.

What can be said about the entropy? In reality, the state operator m is the equivalent of what is called the density matrix in quantum statistical mechanics, which is why Beretta *et al.* define entropy in terms of the operator m log m , where the logarithm is the natural logarithm of the operator m . Specifically, the entropy of the negative of the trace of this operator multiplied by Boltzmann's constant; the authors are able to show that it increases (or does not increase) in the course of time.

So is this a demonstration that the laws of mechanics and of thermodynamics can indeed be combined? Not quite. For one thing, there are various mathematical problems that make some of the steps in the argument conjectural. Worse still, some of the operator functions in the formalism are sometimes undefined. But the system does have the merit of hanging together — the paper now published extends to composite systems the treatment of one-component systems published a year ago.

None of this implies that the arguments about the reconciliation between microscopic reversibility and macroscopic irreversibility will now be stilled. Indeed, while for as long as the present justification of the basis of statistical mechanics holds water, there will be many who say that what Beretta *et al.* have done is strictly unnecessary. But this is a field in which the proof of the pudding is in the eating.

John Maddox

Acquired immunodeficiency syndrome

Laying the groundwork for neutralizing AIDS-linked virus

from Jerome E. Groopman

WITH what success does the human immune system produce antibodies that neutralize the human T-lymphotropic virus type III (HTLV-III) — the virus that is aetiologically linked to the acquired immunodeficiency syndrome (AIDS)? And can the neutralizing antibodies be exploited for prophylaxis or therapy of AIDS? Two papers elsewhere in this issue^{1,2} report that such antibodies are present in some sera both from AIDS patients and from people who have been exposed to the virus but are asymptomatic. The relatively low titres of neutralizing antibodies in HTLV-III-infected persons should not dissuade investigators from pursuing their clinical relevance; the feline leukaemia virus often elicits low titres of neutralizing antibodies *in vivo*,³ yet vaccines of some effectiveness, which exploit at least in part this antibody response, have recently been developed.

Several studies that would help to define the significance of HTLV-III neutralizing antibodies *in vivo* immediately suggest themselves. Comparison of the titres and types of these antibodies in asymptomatic and AIDS patients can readily be accomplished. Particularly interesting would be longitudinal studies to examine whether the neutralizing antibodies persist in the sera of those who remain relatively healthy despite exposure to the virus but diminish in those to progress to AIDS. Of course, the clinical situation may not be so simple. Like visna virus, to which it bears some similarity, HTLV-III may alter its surface antigenic determinants over time and 'escape' from the protective effects of neutralizing antibodies^{4,5}. Serial culture of HTLV-III with testing of neutralizing antibodies on the host's own isolates is one approach to determine if *in vivo* there are selection pressures that favour the emergence of antigenically altered virus. Initial reports of apparently healthy adults in Central Africa who are both antibody positive and virus positive for HTLV-III should make this population particularly valuable in addressing the clinical role of neutralizing antibody⁶. Because antigenic determinants on the gp120 envelope protein of the gp41 transmembrane protein of the virus^{7,8} are likely to be the primary sites of interaction with the putative cellular receptor for HTLV-III^{10,11}, it is to be predicted that neutralizing antibodies are directed against gp120 and/or gp41 determinants. The wide antigenic variability in envelope-related antigens from different HTLV-III isolates¹² makes testing the ability of geographically-distant sera to neutralize geo-

graphically-distant isolates a valuable means of identifying conserved epitopes for neutralizing antibodies.

Recently, a retrovirus that cross reacts in serological tests with HTLV-III has been isolated from African Green monkeys¹³. Studies on the neutralization of HTLV-III by sera from these monkeys and of the ability of human HTLV-III neutralizing antibodies to recognize the surface determinants of the monkey virus may also help to localize highly conserved epitopes that would interact with cellular receptors for the viruses.

HTLV-III, LAV and ARV — all clearly variants of one type of human retrovirus — have been cloned and sequenced, thereby providing ready access to recombinant (made by recombinant DNA technology) viral peptides¹⁴⁻¹⁷. Peptides of the envelope protein can be used *in vitro* to absorb out the neutralizing activity and localize the epitopes that elicit antibodies. It is of interest to determine whether some neutralizing antibodies might react with the putative gene products (termed sor, P', Q and 3'ORF, E', F) that may have functional roles, particularly in the activation of cellular genes (transactivation). The availability of these products will allow the reverse test: do polyclonal or monoclonal antibodies raised in animals against any of these gene products have *in vitro* neutralizing capacity? To obtain the equivalent human antibodies, it may be possible to use B-cells from people with neutralizing antibodies.

Ultimately, *in vitro* studies will be needed to determine the clinical signifi-

cance of neutralizing antibodies for either prophylaxis or therapy of HTLV-III infection. Initial tests of prophylaxis with hyperimmune globulin and of therapy with pools of high-titre neutralizing antibodies can be undertaken in primates which are susceptible to infection with HTLV-III. Simple vaccination with native or recombinant peptides that elicit neutralizing antibodies may not be sufficient to protect primates against challenge with HTLV-III, but such an approach can readily be examined. The role of the cellular immune response (in addition to the antibody response) in preventing or suppressing human retroviral infection is still unaddressed. Inoculation of primates with forms of HTLV-III that are defective in functional genes but still display structural antigens, or with recombinant constructions of HTLV-III with other viruses, such as vaccinia, should permit the study of both cellular immune and antibody responses.

The HTLV-III research community will now coordinate its clinical and scientific forces to build on the new observation of neutralizing antibodies in the hope of constructing strategies to outwit this threatening human retrovirus. □

Lasers

Dynamic holograms from crystals

from Malcolm Gower

WHEN certain crystals are exposed to spatially non-uniform light fields, light-induced refractive index changes occur, caused by the migration and retrapping of charges. Known as the photorefractive effect, the phenomenon was first reported nearly twenty years ago as the mechanism responsible for the self-focussing of laser light in crystals of LiNbO₃ and LiTaO₃, and has since been observed for many more crystals, including CdS, InP and GaAs. It was soon recognized that photorefractive crystals used as three dimensional media for holographic recording (volume holograms) could contain extremely high densities of information,

up to 10¹² bits per cm³, yet retain exposure sensitivities comparable to those of the best photographic emulsions (at least 100 μJ per cm²). But, unlike conventional media, photorefractive crystals can be used for dynamic or 'real-time' holography in which the writing and reading processes occur virtually continuously and simultaneously. Recently there have been some remarkable discoveries in the field that may lead to a host of applications in real-time optical data processing — from optical image amplifiers, enhancers and pattern recognizers to optical switches and memories¹.

Unlike the relatively slow serial proces-

sing that occurs in conventional electronic devices, dynamic holograms allow rapid, parallel-bit processing of information. Because the image wave is a complex or phase conjugate of the subject wave, real-time holography is closely analogous to the nonlinear optical method of degenerate four-wave mixing used in producing phase conjugate (wavefront reversing) mirrors (see Fig. 1a; ref. 2). Thus these crystals can also be used as phase conjugate mirrors to correct distortions on optical wavefronts and to project complex images.

The hologram in photorefractive crystals results from the migrating charges, which may be either positive, as in BaTiO_3 or negative, as in $\text{Bi}_{12}\text{SiO}_{20}$ and $\text{Bi}_{12}\text{GeO}_{20}$. The charges are generated by photoexcitation of electrons or holes from impurity or dopant levels in the band gap of the crystal. The interference pattern set up between the subject and reference waves during recording causes the mobile charges to diffuse or drift (photoconduct) and become retrapped in the darker regions of the interference pattern, leaving behind trapped ionized centres (Fig. 1b). This spatial separation of charge creates local piezo-electrically induced stresses and strains caused by electric fields whose gradients (by Poisson's equation) are a maximum in regions of maximum space-charge density, ρ_{sc} , so that the space-charge field E_{sc} is often phase shifted from the original interference pattern (Fig. 1b). The space-charge field then produces local variations of the refractive index,

Fig. 1 a, Dynamic holography: arrangement for producing real-time holograms and degenerate four-wave mixing phase-conjugate mirrors. **b**, Photorefraction: an interference pattern causes charges produced in bright regions to migrate into and become trapped in dark regions, creating a phase-shifted space charge field, which causes variations in refractive index. The case is shown for negative charge carriers Z is the space coordinate; for other variables see text.

Fig. 2 a, Two-beam coupling in phase-shifted holograms. **b**, High-resolution image projector using a self-pumped BaTiO_3 crystal. **c**, Self-pumped, optically bistable phase-conjugate reflector. **d**, Spatial convolution $\otimes$ and correlation $\odot$. ϵ_1 , ϵ_2 , ϵ_3 are Fourier transforms of the writing and reading beams E_1 , E_2 , E_3 .

Δn , throughout the medium as a result of the linear electro-optic Pockels effect. The hologram may be permanently 'fixed', by applying a biasing voltage across the crystal during recording, or can be erased by uniform illumination of the crystal.

The maximum modulation of both the interference pattern and the induced space-charge field occurs when the recording beams have the same intensity, irrespective of their absolute values. Thus, in contrast to most other mechanisms used to produce phase-conjugate mirrors, the normalized image-wave light intensity (phase-conjugate reflectivity) produced by the reading process is insensitive to the absolute intensity of the recording beam. In BaTiO_3 , for example, which has an extremely large electro-optic effect, an image-intensity gain of 100 has been observed using low-powered continuous lasers³. As the crystal behaves like a phase-conjugate mirror with gain, oscillation could be produced between it and a relatively poor, non-aligned reflector, such as a kitchen spatula. When the spatula is moved, oscillation reappears at its new position, demonstrating that the mirror can automatically track its whereabouts.

If the intensity of the recording reference beam is about half that of the subject beam, then during reading maximum reflectivity for transmitted light occurs near the edges of patterns placed in the subject beam, where the intensities of the two recording beams are equal. Such preferential enhancement of the edges of the image is often beneficial when trying to recognize complicated patterns. Because the rates for holographic recording and erasure depend on the photoconductivity of the crystal, which in turn is proportional to the intensity of illumination, using high light intensities for recording and erasure increases these rates. Thus, in BaTiO_3 , for example, a hologram that takes a few seconds to record using a low-powered He-Ne laser requires less than 10 nano-

seconds when an intense (20 MW per cm^2) pulsed laser is used. On the other hand, provided the crystal is kept dark, the recorded hologram can be stored for long periods, from a few hours to over 10 years depending on the crystal species. Storage is limited only by the dark conductivity of the crystal, which eventually redistributes the charge carriers.

If a weak and a strong beam intersect in a crystal (Fig. 2a), most of the energy in the strong beam can be transferred to the transmitted weak beam (since the Bragg reflection of one wave from the hologram is phase shifted by $\pm \pi/2$ from the transmitted wave of the other, the two waves will interfere constructively or destructively if the hologram is additionally shifted by $\pi/2$). Because the volume hologram written in the crystal is often phase shifted from the original optical interference pattern (Fig. 1b), the two writing beams can exchange energy by their self-diffraction from the hologram. This 'two-beam coupling' effect, although complicating the understanding of many observations in photorefractive dynamic holography, leads to some remarkable effects. For example, in BaTiO_3 , where diffusion processes alone cause charge migration, the hologram phase shift is $\pi/2$ and intensity gains of 600 have been observed for the transmitted weak beam. A two-dimensional laser-beam steering device, using two-beam coupling for the potential random accessing of optical memories, has recently been constructed⁴.

Furthermore, two-beam coupling between a single laser beam and scattered light propagating in the appropriate direction in a BaTiO_3 crystal can lead to self-defocussing or 'fanning' of the beam (see cover picture). If there is total internal reflection of the fanned beam from the far corner of the crystal, phase-conjugate reflections can be produced with a reflectivity of up to 30 per cent by using just one input beam to the crystal⁵. We have recently used such a self-pumped phase-conjugate mirror, with the arrangement

shown in Fig. 2b, to project speckle-free images with submicron resolution. Such a system may be useful in photolithography, as used in the production of silicon chips, for projecting high-resolution images over a large area.

Because two-beam coupling effects are inherent in phase-shifted volume holograms, a self-starting, self-pumped phase-conjugate mirror can be produced by feeding back the transmitted fanned beam to the crystal (Fig. 2c; ref. 6). When the intensity of a separate erasure beam is continuously varied, the reflectivity of this device can have multiple values and exhibit hysteresis effects. This optical bistable behaviour may prove useful for high speed switching and memory elements in future optical computers^{7,8}.

By using lenses to focus and take Fourier transforms of the writing and reading beams, dynamic holography has been used to perform the real time operations of convolution and correlation in crystals of $\text{Bi}_{12}\text{SiO}_{20}$ (Fig. 2d; ref. 9). These operations are extremely useful in complex image pattern recognition, and for image deblurring and enhancement.

Furthermore, by using relatively large intensities to illuminate the subject, dynamic holography in photorefractive media can be used to create a beam that

is the mathematical division of two images¹⁰. By making use of the relatively slow recording and erasure times of these media, it is also possible to perform the real-time subtraction and differentiation of images. Compared to the numerical computational techniques now in use, optical images can in principle be manipulated much more rapidly by direct optical methods.

With their many potential applications in dynamic holography, from optical memory storage and switching to image projection and synthesis, photorefractive media may well produce a revolution no less dramatic than that caused by the discovery of photographic materials over a century ago. □

Immunology

Immune response restored by gene therapy in mice

from Michael Steinmetz

Two classes of cell surface molecules encoded in the major histocompatibility complex (MHC) genes are known to guide T cells of the immune system in their recognition of foreign antigens on cell surfaces. In general, cytotoxic T cells recognize foreign antigens in association with class I molecules, whereas helper T cells co-recognize antigen and class II molecules. The precise molecular interactions that lead to the detection of foreign antigens in the context of MHC molecules (termed MHC restriction) are not known and the role that the MHC antigens play in the development and functions of antigen recognition by T cells is poorly understood. But it is beginning to look as if transgenic mice will provide some answers.

Over the past five years MHC genes, including those encoding for the T-cell restriction elements, have been cloned and sequenced both from mouse and man (see refs 1 and 2). By transfecting genetically distinct cells growing in culture with class I and II genes it has been shown that the molecules they encode function appropriately as T-cell restriction elements³. Currently, these types of gene transfections are being combined with exon-shuffling experiments to identify

which protein domains in class I and class II molecules are recognized by cytotoxic and helper T cells, respectively. One hopes that these experiments, perhaps in conjunction with X-ray crystallography, will eventually define the amino-acid residues that make contact with T-cell receptor molecules and those that may make contact with foreign antigen.

Gene transfer into somatic cells, however, is of limited use. Questions concerning the expression and regulation of genes during development and in differentiated cells, and their influence on the developing individual, are best approached through germline DNA by, in particular, micro-injecting genes into the pronuclei of fertilized eggs (to produce transgenic animals) or using retroviral vectors to transmit genes into early mammalian embryos (or bone marrow cells)⁴. With respect to the immune system there are a series of questions concerning the generation of the diverse repertoire of B-cell and T-cell antigen receptors that can be studied in transgenic animals. In the past two years, several investigators have introduced functional genes for antibody molecules into the mouse germ line to study the tissue and cell specificity of

regulation, and the mechanism of allelic exclusion, of immunoglobulin genes in B cells^{5,7}. Now, transgenic mice have been produced with cloned MHC genes to find out whether the introduced gene can be expressed in a functional way.

Frels *et al.*⁸ have introduced a porcine MHC class I gene into mouse germline DNA and have shown that the foreign gene is accurately expressed in the transgenic mouse. All cells examined display the porcine class I molecule on the surface, and skin transplanted from the transgenic mouse to a normal mouse of the same strain is rapidly rejected. It is known that genetic differences in class I molecules will induce rapid graft rejections — hence they are also termed transplantation antigens. The findings of Frels *et al.* indicate that the porcine class I molecule is recognized by mouse T cells as a transplantation antigen and that the immune system of the transgenic mouse has become tolerant to the porcine molecule. Whether the porcine class I molecule can also function as a restriction element in T-cell-mediated antigen recognition in the transgenic mouse still remains to be investigated.

A related question, namely whether class II antigens encoded by genes introduced into transgenic mice can function as T-cell restriction elements, has now been answered in elegant experiments carried out by three independent groups, two of which describe their results in this issue^{9,10} whereas the third has a paper submitted (L. A. Pinkert *et al.* personal communication). Normally, mice have two different class II molecules, A and E, both of which are composed of distant α - and β -chains. For their experiments, all three groups have made use of strains of mouse that have a 5'-deleted E_α gene and can no longer synthesize the E_α molecule. As a result, their E_β molecules, which are produced as normal, remain in the cytoplasm of the cell rather than forming a heterodimer with E_α on the cell surface. The E_α -deficiency of these mice has previously been correlated with their inability to generate an immune response against certain antigens, for instance to the synthetic copolymer composed of glutamic acid, lysine and phenylalanine (GLPhe).

To perform gene replacement therapy the different investigators used previously cloned intact E_α genes derived from two different mouse strains which contain almost identical E_α polypeptide chains. The intact E_α genes were micro-injected into fertilized eggs of the immune-deficient mice, leading to the birth of a few transgenic mice that contained several copies of the introduced E_α gene. These genes are inherited in a mendelian fashion by the offspring of the transgenic mice, indicating that they are integrated into one autosomal chromosome, and that they are transcribed into messenger RNA molecules of the right size and, more importantly, only in those cells that normally

express class II genes. In contrast to the immune-deficient mice used as recipients, the transgenic mice display an E_a/E_b complex on the appropriate cells indicating that the introduced E_a gene encodes an E_a polypeptide that associates with the host-encoded E_b molecule. Furthermore, Le Meur *et al.*⁹ and Pinkert *et al.* find that the expression of the transgenic E_a gene can be correctly induced in macrophages by γ -interferon. In contrast, Yamamura *et al.*¹⁰ find that the introduced E_a gene and the endogenous E_b gene are constitutively expressed in macrophages. The reasons for the discrepancy are not clear. Taken together, these results show that accurate regulation of the E_a gene can be achieved (despite presumably random DNA integration) with cloned DNA fragments that contain, in addition to the E_a gene, as little as 2 and 1.4 kilobases of 5'- and 3'-flanking sequence, respectively.⁹

The transgenic mice were also shown to have a restored immune response against the antigen GLPhe. Unlike the mice that did not contain an intact E_a gene they could specifically recognize the antigen as measured by T-cell proliferation and antibody production^{9,10}. This shows that reconstitution of the proper class II restriction

element, which is needed to mount an immune response against the particular antigen tested, has been achieved.

These experiments suggest that it will be possible to endow mice with new MHC restriction elements that can function properly in the generation of an immune response. Until now, manipulation of MHC genes in living animals has required the breeding of F_1 hybrid mice, genetic recombination experiments, the time-consuming isolation of mutant mice and the complicated construction of chimaeric mice. Now, new, additional or *in vitro*-modified MHC genes can be introduced into transgenic mice where their effects can be studied *in vivo*. □

Photoelectrochemistry

Quantization effects in superlattice photoelectrodes

from Mary Archer

ARTHUR NOZIK'S strained-layer superlattice photoelectrode, reported in this issue (*Nature* **316**, 51; 1985), is a neat example of technology transfer. Superlattice or multiple-quantum well structures are two-dimensional solids in which thin layers of two different materials A and B, usually semiconductors, are alternated (ABAB) or sandwiched (BAB) one with the other. Electrons localized in ultra-thin (roughly 3–25 nm) semiconducting layers produce unique solid-state physics in superlattice structures, which is now being applied to the possible production of better transistors and solid-state lasers. Nozik has used this unique physics to produce a photoelectrode that could be the prototype of a new generation of photoelectrochemical devices for the conversion of solar energy to electrical power.

What is special about the electrons trapped in a thin-layer region? As every first-year student of quantum mechanics knows, the translational energy levels E available to a particle of mass m in a one-dimensional box of length a are given by $E = n^2 h^2 / 8ma^2$, where h is the Planck constant and n (>1) is the quantum number. An electron localized in a layer of sufficiently small thickness a behaves differently from an electron free to move over larger distances because its energy levels

are coarsely spaced rather than quasi-continuous. In a superlattice structure, the energy levels in the two dimensions parallel to the layers are normal but those in the short dimension through the layers are coarsely spaced. Attractive properties of superlattice devices can be tailor-made in that the electronic and spectral properties are tailored by the thickness of the layers.

All this has been known in principle for decades, but the technology of fabrication of layered structures of good quality, essentially free from the damaging effects of surface states at the A/B interfaces, is much more recent. The production of GaAs/GaAlAs layered structures was pioneered by Bell Laboratories in the 1970s. Strain-free lattice-matched layers of these two materials can readily be produced because their lattice parameters are very similar. However, the number of pairs of materials with good lattice match is very limited. Lattice mismatch at the A/B interface cannot be tolerated because it produces a high density of surface states and superlattice structure of very poor quality. The exploitation of materials with dissimilar lattice parameters has now become possible with the discovery that suitably thin A layers can be epitaxially laid down on B to produce a strained struc-

ture, in which the lattice parameter of A is greater than in the bulk material and is matched to that of B. Fabrication, by molecular-beam epitaxy or metal-organic chemical vapour deposition of strained-layer superlattice structures with acceptably low surface-state density has been developed by the Sandia Corporation, Albuquerque in the past couple of years.

At present there seem to be three main possible applications of these quantum-well structures. The first is the production of a new generation of solid-state lasers. Existing solid-state lasers contain p - n homojunctions within a single semiconductor. Now GaAs/GaAlAs and other A/B heterojunction solid-state lasers of superior properties are being developed. These heterojunction lasers have the potential advantage that the lasing wavelength can be tailored by tailoring the thickness of the doped GaAs layers.

The second application is to the production of better field-effect transistors. Again, GaAs and GaAlAs are most often used. Doping of the active GaAs layer is achieved in a novel way by incorporating the Si dopant in the GaAlAs top layer. Electrons from the Si dopant atoms pass to the GaAs layer, rendering this layer electronically n -type but leaving it free of dopant ions. Thus, there is virtually no impurity scattering of electrons in the GaAs layer and its resistivity, which in a conventionally doped material at low and moderate temperatures is dominated by impurity scattering, is low. Consequently the losses in the transistor are less so that less electrical driving power and heat sinking are required.

The third possible application is to heterojunction photovoltaic detectors that could be fabricated on a chip and would be particularly suitable for use in combination with optical fibres. These have maximum transmission at about 0.8 eV so Si-based photovoltaic detectors,

Superlattice structure consisting of alternating layers of GaAs_{0.45}P_{0.55} (dark layers) and GaAs_{0.75}P_{0.25} (light layers) that are 275 and 300 Å thick, respectively. The light layers form quantum wells and the dark layers potential barriers (photo courtesy of K. Jones).

with a band gap of 1.1 eV, cannot be used.

Reverting to photoelectrochemistry, quantum size effects produced by very small (<10 nm) semiconductor particles have already been reported. Nozik now describes the first quantum size effects produced in a photoelectrochemical system using a superlattice structure (see figure). The onset of photocurrent from a conventional GaAs thick-layer photoelectrode occurs at the band edge (1.42 eV) of the material, rising monotonically to a saturation value at lower wavelengths. The photocurrent action spectrum (fig. 3 of Nozik's article) of the GaAs/GaAsP strained-layer superlattice photoelectrode is quite different, showing the multiple peaks that should result from transitions between the discrete energy levels in the quantum wells.

Is this photoelectrode useful or merely interesting? It is hard to answer this question as yet. Its present quantum efficiency is poorer than that of a conventional bulk GaAs photoelectrode. On the other hand, the ability of superlattices to absorb photons of discrete energies provides a means whereby higher solar-energy con-

version efficiencies might be achieved. Conventional photoelectrodes degrade the energy of absorbed photons of energy $E > E_g$ to the band-edge energy E_g , thereby dissipating a significant fraction of solar energy as heat. This could be avoided in a superlattice photoelectrode because carrier relaxation to the semiconductor band edges should be inhibited by the presence of discrete energy levels with relatively large separation.

Two-dimensional solids are also excellent vehicles for basic physics. Their fabrication by molecular-beam epitaxy and chemical-vapour deposition is being investigated in several laboratories. "A lot of new physics will come out of two-dimensional solids" says Dr Michael Pepper, the leader of the Cavendish Laboratory's team. "For example, optical logic devices, in which thin layers are optically switched between a non-absorbing and an absorbing state, become an attractive possibility". □

Muscle structure

First sight of crossbridge crystals

from Roger Craig

TO DESCRIBE the precise atomic interactions responsible for generating the force that drives muscle contraction is the dream of muscle biologists. X-ray crystallography of contractile proteins should provide the answers but the purified proteins tend to form polymers, similar to those in muscle filaments, rather than the necessary crystals. Nevertheless, the structures of three components of the thin filaments — tropomyosin, troponin-C and actin — have all recently been resolved at atomic or near-atomic resolution (see ref. 1). And now, I. Rayment and D. M. Winkelmann have obtained and begun to analyse crystals of the head of myosin, the pivotal protein in contraction^{2,3}.

The head or subfragment-1 (S1) of the myosin molecule is the energy-transducing component of the contractile machinery and constitutes the cross-bridges, the cyclic interaction of which is responsible for the sliding of the actin filaments past the myosin filaments during force generation. There are two heads attached to one long tail in each myosin molecule; the tail is an alpha-helical coiled-coil which aggregates with other tails to form the backbone of the thick filament, whereas the heads are globular units, each comprising a heavy chain and two light chains, which together contain the sites for ATP hydrolysis and actin binding. The heads can be cleaved from the tail by proteolysis.

Myosin itself has never been crystal-

lized but much has been learnt from analysis of the purified heads and tail. Two-dimensional crystals (paracrystals) of the tail and its amino-acid sequence reveal repeating periodicities in the myosin filament backbone⁴. S1 is found to be an elongated (200 Å), curved, pear-shaped entity in the electron microscope (for example refs 5,6), although solution X-ray scattering⁷ suggests a somewhat different appearance.

But the crystallization of S1 has consistently eluded muscle researchers, leading to an assumption in some circles that the molecule could not be crystallized. Therefore, the two papers by Rayment and Winkelmann^{2,3} represent an unexpected breakthrough. Crystals of S1 diffracting to

at least 4.5 Å resolution have been grown by careful attention to the source of myosin and method of proteolysis. The relatively pure fast-twitch chicken pectoralis (breast) muscle was used as starting material, rather than the mixed-fibre muscles that are used in the more conventional rabbit myosin preparation. Hence, the myosin isozyme population was presumably more uniform than usual. Papain, in the presence of divalent cations, was used to digest the myosin instead of the more commonly used chymotrypsin. In this way S1 retains both of its light chains, known from other studies to be important in stabilizing the 'neck' region of the myosin head (chymotrypsin causes loss of one of the light chains).

It will no doubt be several years before the high-resolution structure of S1 is available. Meanwhile, in a departure from normal protocol, Winkelmann *et al.*² are studying the crystals by electron microscopy and resolving long-standing uncertainties⁴⁻⁷ about the gross structure of S1. From electron micrographs of fixed and embedded crystals sectioned in selected crystallographic planes, the authors have produced low resolution (about 30 Å) images of S1 in three different projections. Significant is the fact that optical diffraction patterns of the micrographs are similar to the X-ray patterns of the native hydrated crystals showing, reassuringly, that the micrographs present a reasonably faithful image of native S1 at 30 Å resolution. The most informative view of the crystal is that looking down the *a* axis (see figure). In this projection the long axis of the S1 molecule lies approximately in the plane of the section, and S1 molecules at different depths in the section are virtually superimposed on one another. Thus, each stain-excluding tadpole-shaped structure is effectively a projection of a single S1 molecule viewed through its thinnest dimension.

The overall shape and size of S1 can be deduced from these sections. The molecule is curved and its contour length is at least 160 Å (probably longer), providing direct and strong support for the shape and length seen in electron micrographs of shadowed myosin⁵ and in reconstructions

Filtered image of an electron micrograph of a S1 crystal, looking down the *a* axis. The 'negative' contrast of this specimen (protein, white; solvent regions, black) is a feature of the tannic acid/glutaraldehyde procedure used to fix the crystals (courtesy of D. A. Winkelmann).

of actin 'decorated' with S1 containing both light chains⁶. It is about 60 Å at its widest, tapering distally to a less dense neck region where the light chains are located and where attachment to the tail would occur^{6,8}. This length implies that shorter estimates, based on solution-scattering data⁷, are incorrect: it seems likely that these data do not readily pick up the presence of the thin part of the myosin head.

These electron microscope studies of the crystal represent only the beginning. The authors are extending their work to a full three-dimensional reconstruction of S1 based on tilt views of the crystals. As heavy-metal derivatives and higher resolution X-ray data are obtained, the three-dimensional courses followed by the heavy and light chains should become visible. Hopefully, the structural mechanism of ATP hydrolysis will be clarified. But the culmination should be when the three-dimensional structure of S1 is brought together with that of actin: then it may be possible to decipher the nature of the

activation of the myosin ATPase by actin and possibly even to deduce the kind of structural change that occurs when these molecules interact to produce force. Meanwhile these preliminary studies both whet the appetite and strongly support the gross picture of S1 suggested by electron microscopy. They also reassure electron microscopists (and their critics) that molecular structure can be well preserved even when proteins are stained, dehydrated and observed with an electron beam under high vacuum. □

Crystallography

Some answers but more questions

from A. L. Mackay and P. Kramer

THERE has been an exponential explosion of activity among crystallographers following the report by D. Shechtman *et al.*¹ of a splat-cooled Al/Mn alloy showing, over extended regions, electron diffraction patterns of full three-dimensional icosahedral point symmetry. Some 25 follow-up papers, mostly preprints, are in circulation and several high-resolution micrographs of this material have been published. It remains to be seen whether the structure implies a conceptual revolution, a change of paradigm or just a shock to our complacency.

On page 50 of this issue, L. A. Bursill and Peng² publish a micrograph in which the spots fit very closely to the points in the 2-dimensional Penrose quasi-lattice (which is a section of the 3-dimensional icosahedral pattern). One characteristic feature is the arrangement of spots in a regular decagon, of diameter 14.5 Å, with an isosceles (non-equilateral) arrangement of three points inside. We might contrast this with the micrograph of the Sendai group³, where the triangles inside the rings are not resolved but which shows order over a larger area and where the long-period modulations show up clearly.

For the interpretation both of diffraction patterns and of micrographs, the problem of double diffraction is crucial⁴, as can be seen by considering five sinusoidal density waves at 72° to each other in the plane. The transform is a ring of 10 spots. If the diffracted waves are scattered again in the same specimen, the resulting diffraction pattern, the convolution of the

ring of 10 spots with itself, accounts for almost all of the observed diffraction spots (and repeated diffraction would account for the remainder). Thus, both diffraction patterns and micrographs tend to be self-similar, with ratios of the golden number, and it is difficult to decide which is the primary level.

Nevertheless, P. A. Bancel and others⁵ have obtained powder X-ray diffraction patterns using synchrotron radiation and claim to have eliminated multiple diffraction effects. Their powder pattern is indexed with six integer indices with respect to six axes (parallel to the 5-fold axes of the icosahedron). Given the earlier demonstration⁶ of how to handle standard crystallographic calculations with redundant axes such as these, the planes corresponding to the [10000] reciprocal-lattice vector turn out to have the spacing of 2.17 Å. The intercepts of this plane on the icosahedral axes, corresponding to the edges of the Penrose tiles, are $\sqrt{5}$ times as great, namely 4.85 Å, which fits reasonably with a 14.5 Å diameter for rhombic triacontahedra and would give about 5–6 atoms per acute rhombohedron. Portier and others report an edge-length of 4.60 Å for the proposed Penrose rhombohedra.

The relative stability of quasi-lattice and of normal crystalline phases has been investigated both experimentally and theoretically. G. Parthasarathy and the group in Bangalore report⁷ that high pressure (5–9 GPa, varying with composition) irreversibly converts the icosahedral phase to the crystalline, indicating that the

former is metastable. The electrical conductivity increases sharply on compression. The existence of phases ranging from fluid to crystalline has been explored by G. S. Emch and others⁸ in terms of algebraic quantum theory; it would be of interest to see applications of this theory to quasi-crystalline phases. Bak⁹ has applied the Landau theory of phase transitions to the icosahedral structures.

One of the characteristics of these icosahedral structures is now recognized to be a conflict, of a kind foreseen by, for example, A. Janner¹⁰ and D. R. Nelson¹¹, between the requirements of local and long-range ordering. (These ideas go back to those of G. Toulouse *et al.* on the topology of glasses.)

Questions of crystallography in two and three-dimensional non-Euclidean manifolds now arise. We have already seen beautiful examples of crystallography in two-dimensional manifolds in the series of papers by S. Andersson and colleagues¹² on periodic minimal surfaces; as there is a third dimension of the world of ordinary experience into which planar patterns may be curved, these provide a way of acquiring experience before trying to make sense of three-dimensional non-euclidean manifolds. But J. F. Sadoc and R. Mosseri¹³ suggest that there is an ideal structure, curved into a fourth dimension which, by disclinations, can be flattened back into ordinary space to give an icosahedral phase. This idea has still to be examined carefully, but we may well be seeing the emergence of 'non-euclidean crystallography'.

Another approach to the interpretation of the experimental results is in terms of projections onto three dimensions of six-dimensional regular crystals. N. G. De Bruijn¹⁴ (for two dimensions) and P. Kramer¹⁵ (for three dimensions) before Shechtman's discovery; and V. Elser¹⁶, and R. K. P. Zia and W. J. Dallas¹⁷ afterwards, have derived the Penrose pattern (a non-periodic tessellation of space by acute and obtuse rhombohedra of two kinds) by projection of a primitive lattice in six dimensions. The resulting pattern was called¹⁸ a 'quasi-lattice' because any vertex can be given integral indices with respect to six axes (three redundant) and corresponds to Frank's consideration of the usual hexagonal lattice (with four axes, one redundant) as the projection of a four-dimensional lattice¹⁹. The pattern is characterized by the algebraic integers which are the golden number, $\frac{1}{2}(1 + \sqrt{5})$, and its reciprocal. As the real space pattern thus involves two irrationally related steps in the same direction, the diffraction pattern resembles the convolution of these two lattices. In the light of Coxeter's discussion of zonohedra as shadows of higher-dimensional polytopes²⁰, are we back with Plato²¹ looking at shadows of reality cast on the wall of our cave?

In the icosahedral structures being

investigated spatial ordering is imperfect, but ordering of the directions of nearest-neighbour bonds persists over long distances. The three-dimensional Penrose pattern can be converted into a nematic texture by leading threads across each tile from face to face. There are 15 directions of these threads, corresponding to the 30 faces of the rhombic dodecahedron which is the basic element of the geometry of the pattern, and which connect pairs of opposite faces. Six layers each containing five sets of threads would be strongly expressed²². The construction resembles the rod packing described by M. O'Keefe and S. Anderson²³ where rods run in the four [111] directions of a cubic structure. In the icosahedral nematic texture, icosahedra connected by edges might represent thread directions²⁴; dislocations would involve line defects²⁵.

So we now have on the cards a number of theories and partial explanations of the icosahedral structures (though D. Levine and P. J. Steinhardt²⁶ suggest that other symmetries may also be possible) of which the following ingredients may have to be dissected and combined:

- Multiple twinning²⁷.
- Hierarchical packing of icosahedra³.
- Bond-orientational order²⁸.
- Three-dimensional packings of the Penrose type, probably with disordering^{18,26}.
- Icosahedral nematic ordering²⁴.
- Hypergrid descriptions and bounded projections of n -dimensional lattices (refs 14–16, 29, 30).
- Incommensurate (modulated) structures¹⁰.
- The flattening into ordinary euclidean space of structures which appear more perfect in a curved metric¹³.

A whole string of questions has arisen and will have to be answered before the observations now to hand are understood. What is the ideal complete ordering of the icosahedral structure, and is it really the three-dimensional analogue of the Penrose pattern? What is the actual quasi-unit-cell edge? What is the nature of the disordering from this ideal structure? And what does it mean physically that a three-dimensional structure should be the (bounded) projection of a structure of higher dimensionality, or even the result of the flattening of a structure curved out of normal space?

Further ahead is another set of questions. What are the requirements leading to the formation of icosahedral phases? Are there others with similar kinds of order? Already there are reports of degrees of order for the Al/Mn material intermediate between the icosahedral and the crystalline. How can the structure best be handled mathematically, in particular for the calculation of structure factors for comparison with experiment after allowance for double-diffraction effects? And what are the physical properties we might

expect from materials such as these?

Let us enjoy a wide-ranging bout of speculation before the definitive answers emerge from crucial observations. For it is too rarely that we see such a stimulating experiment as Shechtman's¹. □

Animal behaviour

The serpent's seductive scent

from Daniel I. Rubenstein

ANIMALS are not always what they appear to be. Insects often blend into the foliage by looking like twigs or leaves; small hawkmoth caterpillars transform themselves into formidable snake-like creatures by inflating their heads to reveal large eye-like markings; and palatable butterflies, such as the vicory, can so closely resemble noxious species, such as the monarch, that they reduce their risk of being eaten without incurring the cost of acquiring and maintaining toxic substances. Clearly, deceit can help in fooling predators. Recent research, including that described on page 59 of this issue¹, shows that it can be just as useful in duping conspecific competitors.

During the past few years it has become clear that even within populations, marked differences exist in the way individuals compete for reproductive opportunities. Both theoretical^{2,3} and empirical⁴ studies have shown that the reproductive success of males adopting alternative breeding strategies can sometimes equal that of males displaying the typical form of behaviour of a species. For this to be the case, the alternative strategy, which frequently entails forgoing immediate breeding opportunities, must compensate by avoiding some of the costs and risks associated with the typical strategy. Success usually comes by copulating surreptitiously, with perhaps the best form of stealth being to adopt the guise and behaviour of females.

Such female mimicry occurs commonly in bluegill sunfish^{5,6}. In this species the dominant breeding males are large and light in colour — they build nests, drive other light-coloured males away, actively court females and provide parental care.

Other males, however, mate by parasitizing spawning pairs. These individuals are smaller, look like the more darkly coloured and vertically barred females, and simply sidle up to the spawning pair and release sperm as the female deposits her eggs in the nest of the dominant male.

Mason and Crews¹ here show that serpents have added a new seductive twist to female mimicry. Normally, mimicry enables subordinate males to hide from aggressive dominants and thus gain access to receptive females. In the garter snake, however, female-mimicking males are more than just wolves in sheep's clothing.

Male garter snakes, *Thamnophis sirtalis parietalis*, rub their chins along the backs of females during courtship. This behaviour is a specific bioassay for the snake's attractiveness pheromone. Here, three males are courting a female while a fourth has become confused and is courting a 'she-male'. Photo by D. Crews.

Not only do they increase their chances of mating with the receptive female by donning her scent, but they actually seduce, and lure, normal males away from her.

In garter snakes, courtship takes place in writhing mating swarms, or balls; each female is courted by many mates (see figure). Mason and Crews report that many of the mating swarms they studied lacked females; instead, one of the males was being courted by the others. These courted males, or 'she-males' are morphologically indistinguishable from true males, and have higher levels of testosterone and lower levels of oestrogen than true females. Yet these she-males have active female-like pheromones: the pheromone from the skin of she-males is as effective in eliciting courtship from males in experimental arenas as is the pheromone extracted from the skin of females. She-males, however, are not as sensuous as true females. When males are given a choice between a female and a she-male, only about 20 per cent of the males court the she-male. Nevertheless, she-males have a tremendous reproductive advantage. When groups of males and she-males are allowed simultaneously to court an attractive female, approximately 70 per cent of the trials end with matings by she-males. Casual observations of mating balls composed of all three classes of snakes indicated that the she-males actually seduce some males and entice them to court the she-male instead of the normal female.

So far only the seductive effect of she-males on 'he-males' has been examined. Such interactions would have predominated in natural populations when she-males first appeared and were the rarest sexual form. Given the reproductive advantage that she-males show in such interactions, the rapid proliferation of she-males seems inevitable. The effect that she-males have both on other she-males and on true females should be investigated. Do she-males interfere with the reproduction of other she-males to an even greater extent than they do with males? Do females treat she-males differently from he-males? Also, are there ecological factors that limit the viability of she-males? If behaving like a she-male truly entails no costs, however, then an evolutionary problem emerges: why aren't all males she-males? The answers to these questions will be necessary for a complete understanding of the phenomenon Mason and Crews have described. □

THIS engraving of an American white pelican by John James Audubon is included in the reissue of six engravings of North American birds and in an exhibition at the British Museum of Natural History. Both mark the bicentenary of Audubon, North America's most famous naturalist. His *Birds of America*, consisting of 435 hand-coloured plates, was first published in London between 1828 and 1839. Audubon travelled over the whole United States, painting life-size pictures of native birds, many never described before. The plates were engraved on Double Elephant (991 × 673mm) copper sheets and one edition of 200 copies was printed. Most of the plates were destroyed but the American Museum of Natural History owns 12, six of which have now been restored. The money raised by selling the new issue will finance an Audubon fund at the American Museum of Natural History. The exhibition at the British Museum of Natural History, entitled "Drawn from Life", runs from 3 July to 28 September, 1985.

Stellar evolution

Brown dwarfs and hidden mass

from R. J. Tayler

Is it possible that much of the hidden matter in the solar neighbourhood and elsewhere in the Universe is composed of brown dwarfs, low-mass subluminescent stars that do not become hot enough for nuclear fusion reactions? Until recently no brown dwarfs had been identified. Now infrared observations suggest that the star Van Biesbroeck 8B is such a brown dwarf. On page 42 of this issue L. A. Nelson, S. A. Rappaport and P. C. Joss support this identification by providing detailed calculations of the possible structure and evolution of this star.

It is generally agreed that stars whose masses are less than about a twelfth of a solar mass, the precise limit depending on the chemical composition and on some uncertainties in the physics of stellar interiors, do not attain a high enough central temperature for a useful release of nuclear energy. As a result they have only a short life as stars with significant luminosity, whereas stars whose masses are just above the limit have a very long main-sequence lifetime. The process of star formation is complex and not very well understood; it is not clear whether large numbers of stars will form below the mass limit, although some studies of the fragmentation of gas clouds have suggested that the minimum stellar mass formed might be significantly smaller. If that is true, a substantial amount of matter in the Universe could be in the form of these subluminescent stars, the brown dwarfs.

There appears to be hidden mass throughout the Universe. More than fifty

years ago, Oort pointed out that the strength of the gravitational field perpendicular to the disk of the Galaxy in the solar neighbourhood implied a local mass density greater than that provided by luminous matter. Although much interstellar gas has been discovered since then, there still appears to be hidden mass in the solar neighbourhood. In addition, the variation of rotation velocity with distance from galactic centres implies that many galaxies have higher masses than expected. Finally the dynamics of groups and clusters of galaxies indicates the existence of hidden mass on a much larger scale. It is difficult for all of this matter to be baryonic, if the hot big-bang cosmological theory is valid, but some of it certainly can be, so it is of interest to ask whether brown dwarfs are an important constituent of the Universe.

Brown dwarfs must be difficult to detect unless they are close to the Sun and previous discussions of their probable numbers has been based on estimates of the numbers of low-mass luminous stars. For masses close to and greater than that of the Sun, the number of stars in unit-mass range in a given volume of space increases rapidly with decreasing mass. This mass function must turn over at some low mass so that the total mass in the solar neighbourhood is not impossibly large, but the crucial question is whether this turnover occurs above or below the limit for nuclear reactions. Observers are not agreed on this point. G. Gilmore, N. Reid and P. Hewett (*Mon. Not. R. astr. Soc.* **213**, 257;

1985) are confident that the hidden mass cannot be in the form of dwarfs, whereas J. N. Bahcall, P. Hut and S. D. Tremaine (*Astrophys. J.* **290**, 15; 1985) believe that brown dwarfs are the best candidate.

It seems possible that some of these questions will be answered now that brown dwarfs have been observed. For some time infrared observations have provided candidate objects (see, for example, T. O. Boroson, M. S. Giampapa and J. Liebert, *Astrophys. J.* **283**, 758; 1984) but no definite identifications. Now there seems to have been a definite detection in Van Biesbroeck 8B, the companion to another very low-mass nearby star Van Biesbroeck 8A. The identification has been made using infrared speckle interferometry by D. W. McCarthy Jr, R. G. Probst and F. J. Low (*Astrophys. J.* **290**, L9-13; 1985). Now Nelson and his colleagues describe detailed models of the structure and evolution of very low mass

stars, and show that the observed luminosity and surface temperature of Van Biesbroeck 8B are consistent with its having a mass of about 0.06 solar masses and an age of about 2×10^9 years, comfortably less than the age of the Galaxy. They also suggest that the mass of Van Biesbroeck 8A is very close to the hydrogen-burning limit.

It is obviously of great interest to know that brown dwarfs do exist and to have the opportunity to check the models of low-mass degenerate stars against observations. One or two stars do not, however, account for the hidden mass, so observers will be looking for every opportunity to discover further objects to obtain estimates of their space density. As Nelson *et al.* point out, the Hubble Space Telescope and the Space Infrared Telescope Facility may provide such opportunities. □

Evolutionary biology

Costs of reproduction

from Linda Partridge and Paul H. Harvey

MOST genetic models for the evolution of life-history patterns assume that an organism's reproduction early in life has a negative effect on its later reproduction. Therefore, reproductive rates at all ages cannot be simultaneously maximized by natural selection^{1,4}. One physiological basis for this effect may be that early reproduction diverts resources away from growth and repair, so that survival rates and fertility are subsequently lowered. Different life-history patterns can evolve as a consequence of reproductive trade-offs. For instance, if growth rates are reduced when an organism's resources are channelled into reproduction, but fertility increases with an individual's size, natural selection may favour delayed maturity and hence higher reproductive success at maturity. Conversely, if larger individuals attract the attention of predators, then early reproduction may be favoured.

These notions of reproductive costs and trade-offs provide an evolutionary explanation for the observed diversity of age-specific reproductive patterns, but until recently there has been little empirical testing of the hypothesis. Attempts to demonstrate and measure the costs of reproduction are producing what at first sight seem to be mixed results.

One major category of study examines correlations between early and late reproduction among different individuals (or clones, populations or species) living in the wild or in captivity. Both negative and positive correlations have been found. For example, the overwinter survival rates of female song sparrows (*Melospiza melodia*) that have reared broods of different sizes are positively correlated with brood size⁵.

Similarly, early and late fertility are positively correlated with survival both in and among clones of a planktonic rotifer (*Platyias patulus*)⁶. In contrast, female red deer (*Cervus elaphus*) calving in one breeding season have a reduced probability of survival to the next breeding season and, if they do survive, of then calving⁷. Only 22 of 33 such studies cited in a recent review⁸ suggest that reproductive costs do occur. But correlation is not causation, and the other studies can be interpreted on the basis of a cost of reproduction if a third variable acts simultaneously on early and late reproductive rates. For instance, individuals may differ in size, nutritional status or their fit to the habitats they occupy, particularly in the laboratory. Under such circumstances, rates of early and late reproduction may be positively correlated, because of their common correlation, with a third variable.

Therefore, when investigating costs of reproduction, it is essential to perform manipulative experiments in which other confounding variables are kept constant⁸⁻¹¹. Laboratory studies with male fruitflies (*Drosophila sp.*) provide an example of manipulations that can demonstrate costs to reproduction when the correlational evidence seems to point in the other direction. The natural correlation between longevity and age-specific reproductive activity in males is positive, because both variables are strongly correlated with body size¹². When reproductive activity is manipulated by allowing males access to an excess of sexually receptive females, rates of survival are reduced¹³. Similarly, female *Drosophila* that lay few eggs because they are kept virgin¹⁴,

or are made sterile by high temperatures¹⁵ or radiation¹⁶ have higher survival rates than females reproducing normally. Similar experiments have manipulated clutch sizes of birds in the field and hence the effort expended on parental care. One study on blue tits (*Parus caeruleus*), outstanding for its careful experimental design and large sample sizes, showed that large clutches result in weight loss and increased mortality in female but not male parents, possibly because although both sexes feed the nestlings, only the female incubates¹⁷.

Genetic manipulations of reproduction have also revealed costs. *Drosophila* females selected for high fertility late in life show increased longevity and lowered early fertility^{18,19}, and females with high fertility early in life have low longevity²⁰.

The general conclusion from properly conducted experiments is that reproduction does have costs; genetic variation has been found in the few cases where it has been looked for, thus providing the raw material for the evolution of reproductive trade-offs. Nevertheless, adequate tests of the importance of reproductive trade-offs in life-history evolution will entail experimental work under field conditions. Laboratory studies probably tend to underestimate reproductive costs, because many important features of field conditions, such as competition for food, predators and competitors are usually absent. However, making the relevant manipulations under field conditions can be extremely difficult. For instance, it is relatively easy to alter clutch and brood size in birds by addition or removal of eggs or nestlings, and hence to measure costs of parental care, but manipulation of the rate of egg laying to assess costs of egg production would be more difficult. Although there are few field studies of reproductive costs, only this type of information will allow adequate tests of some fundamental assumptions of life-history theory. □

Is the AIDS virus recombinant?

SIR — The retrovirus which is the causative agent of acquired immune deficiency syndrome (AIDS) has recently been shown to be distantly related to the C-type retrovirus^{1,4} and rather share nucleotide sequence homology with the visna virus, a slowly replicating and pathogenic but non-oncogenic retrovirus of sheep that is a member of the Lentivirinae subfamily⁵. The phylogenetic tree inferred from the amino-acid sequences of the DNA endonuclease domain of the retroviral *pol* gene product showed that the AIDS virus is evenly separated from human T-cell lymphotropic virus type-I (HTLV-I) and Rous sarcoma virus (RSV)⁶ (our phylogenetic tree inferred from the same domain differs slightly from that of Wain-Hobson *et al.*⁶; the most distant relative is Moloney murine leukaemia virus (M-MuLV) rather than the AIDS virus). Essentially similar phylogenetic trees were also obtained from the comparisons of the reverse transcriptase domain and highly conserved regions of *gag* gene product, although they differ slightly from each other in tree topology.

In the light of these phylogenies inferred from the *pol* and *gag* sequences, the *env* gene products of the AIDS virus and murine mammary tumour virus (MMTV), a B-type retrovirus, show unexpected homology patterns. The *env* gene product comprises an N-terminal highly divergent region encoding a envelope glycoprotein (gp70 in M-MuLV) and a C-terminal conserved region coding for p15(E), known to be membrane-associated and anchor gp70 at the virion surface^{7,8}. A marked homology is seen in the membrane-associated region between C-type retroviruses (in Fig. 1a, only the homology matrix⁹ of pair M-MuLV/HTLV-I was shown). Although MMTV bears close resemblance in endonuclease sequence with RSV^{6,10}, no obvious homology has been detected in the

Fig. 2. Alignment of amino-acid sequences of *env* gene products among distantly related retroviruses. *a*, Homology maps along the sequence of *env* gene product. Homologous segments were indicated by vertical lines as well as filled boxes, dotted boxes or hatched boxes. The *env* gene products were tentatively divided into two regions, I and II, as in Fig. 1. *b*, Alignment. For each of the homologous segments shared by different viruses as shown in *a*, their amino-acid sequences were aligned as described previously⁹. Boxed residues indicate identities or favoured amino-acid substitutions among more than half of the viruses. —, Gap; ● and ○, positions that are occupied by identical amino acids and identical or chemically similar amino acids among all the viruses compared, respectively.

env region (Fig. 1b), suggesting that MMTV is a hybrid. Comparisons of the AIDS virus (HTLV-III) with C-type viruses and MMTV revealed unexpected homologies in the membrane-associated region. Evidently homology of the AIDS virus with other viruses drastically changes at a point around amino-acid positions 566–582 (HTLV-III¹ of the *env* gene product). In the regions before this point, the AIDS virus exhibits homology with C-type viruses, but not with MMTV (Fig. 1c). In contrast the AIDS virus shares homology with only MMTV

beyond this point (Fig. 1d). These results are summarized in Fig. 2a and alignments of the homologous regions are shown in Fig. 2b. This mosaic structure of the AIDS virus strongly suggests that genetic recombination occurred between a member of C-type virus and a B-type virus related to MMTV during evolution, generating a novel type of retrovirus, the AIDS virus.

Our proposal that the AIDS virus is a recombinant of B- and C-type retroviruses is consistent with evidence^{2,14} that both the AIDS virus and MMTV use tRNA^{lys} as a primer for (–) strand synthesis instead of tRNA^{pro} used by other mammalian retroviruses, and that they contain very similar polypurine tracts. To confirm further, we searched amino-acid sequence similarities between the AIDS virus and MMTV beyond the membrane-associated region. Somewhat less extensive but significant homology has been detected (positions 712–742 of HTLV-III *env-lor*¹ and 239–269 of MMTV LTR ORF¹³). Their amino acid sequences

VNRVRQGSPLSFQTHLPPIRGDFRPEGIEE (HTLV-III)

VNGYKVLRYSLPFRERLARARPFWCMSQEE (MMTV)

share 32% homology with the probability of occurrence by chance of less than 2.2×10^{-5} .

It has recently been demonstrated that sequence homology and morphologic similarity exist between the AIDS virus and visna virus⁵. Direct sequence comparison of these viruses together with

Fig. 1 Homology matrix comparisons of amino-acid sequences of *env* gene products of four retroviruses. 1, M-MuLV¹¹ (ordinate) against HTLV-I¹² (abscissa); 2, M-MuLV against MMTV¹³; 3, HTLV-III¹ against HTLV-I; 4, HTLV-III against MMTV. The homology matrices were calculated by the method described previously⁹. Each diagonal line indicates a segment 25 residues long that shows similarity above a threshold level which corresponds to the degree of similarity that would occur by chance with a probability of less than 1.0×10^{-5} . Arrows indicate regions where significant sequence similarities were observed; per cent homology and the probability of occurrence by chance are respectively 40% and $<10^{-9}$ for 1; 37% and 7×10^{-9} for 3; 37% and 4×10^{-7} for 4. No significant similarity was observed for 2. Since HTLV-III exhibits a mosaic pattern of homology with HTLV-I and MMTV, the *env* gene products were tentatively divided into two portions

R 43A

MMTV will be of particular interest in relation to our present proposal.

Prediction of protein structure from sequence

SIR—In a recent News and Views article, Stephen Harrison¹ urges caution “in predicting aspects of protein structure from sequence, what we need to recognize are entire domains or significant sub-domains—not just elements of secondary structure”. He also points out “The poor correlation between local sequence and secondary structure has been aptly demonstrated by Kabasch and Sander², who show that the same pentapeptide in different proteins has fundamentally different backbone configurations in each”.

I wish to point out two items which should caution the reader against accepting such advice without question.

In our original paper on the prediction of protein secondary structure³ (also see ref. 4), it was pointed out with great care that any specific sequence, for example five residues, will assume a conformation dependent upon the neighbouring sequences on both the amino and carboxyl termini until a sequence is reached, of usually four residues, which will either change conformation (β -turn), or will be unable to maintain a secondary structure [$\langle P_{\alpha} \rangle$ or $\langle P_{\beta} \rangle < 1.0$]. Thus it is an expected observation, rather than a novel finding, that a pentapeptide, joined to different sequences may assume dissimilar conformations. Thus the Kabasch and Sander² discovery, used to discredit predictive schemes, reaffirms rather than discredits the predictive algorithm. Harrison's¹ emphasis on domain structure rather than secondary structure to evaluate biological functional units has been expounded with great elegance by Rossman⁵ and is a well accepted theme. However, domains are constructed by in-

teractions of secondary structures; so let us not put the cart before the horse. To understand the formation of domains one must know the secondary structures first. Thus before one has a complete three-dimensional structure of a protein, derived from X-ray crystallographic studies, it can be extremely useful to predict secondary structures and look for homologies with other proteins to find interesting relationships.

I agree with Harrison¹ that the paper of Kabasch and Sander² should be carefully read as it displays how a false conclusion can be drawn from an interesting fact.

On the possibility of inductive probability

SIR—We here make a second attempt to explain the reason for our hesitation in accepting the Popper-Miller thesis¹. We agree with all of their mathematical relations. Our problem is with the interpretation. We offer again two reasons and frame them here without using the negative signs of our first letter², which appear to have drawn excessive attention to themselves.

First, consider the (correct) result for $p(e) < 1$

$$s(h \leftarrow e, e) \equiv p(h \leftarrow e|e) - p(h \leftarrow e) < 0 \quad (1)$$

Popper and Miller identify the ampliative (or “loosely speaking inductive”) part relative to any evidence, e of any hypothesis h , with $h \leftarrow e$ given e . They infer from (1) that that part of h which goes beyond e is always countersupported by e . (We use their wording in both these sentences.) Our difficulty with this is that $s(k \leftarrow e, e) < 0$ for all values of k and in particular for $k = h$ and $k = \bar{h}$. One might have expected that if the inductive part relative to e of h is countersupported by e , then it would at least be possible for the inductive part relative to e of $\bar{h}$ to be supported by e . But on Popper and Miller's interpretation the inductive part relative to e of both h and $\bar{h}$ is always countersupported by e . This suggests to us that there is something astray with this interpretation, and it led us to observe in ref. 2 that a different definition of terms or some restriction on their interpretation seems to be required. Our interpretation of (1) was explained in our comment on our theorem A, and is rather simple: Since $p(h \leftarrow e)$ still allows $\bar{e}$ to occur, (1) shows that this probability is reduced if $\bar{e}$ is ruled out.

Second, one can understand the import-

ance of discussions of the extent to which 10 or 20 supportive occurrences e support a hypothesis h as a general statement, as is done in statistical theory. If a penny comes up “heads” 10 times ($e_1, e_2, \dots$) is it a penny with two heads (h)? There is a structured relation between e and h . It is, however, difficult to see how statements about induction can go very far if they are based only on probability algebra which leaves h and e as arbitrary propositions. In our letter we noted that the arguments in this correspondence had used only probability algebra, and that they involve the handicap of being independent of any inferential relationship between e and h .

Mathematically speaking, we would say that the support function $s(x, y)$ is indeed useful, as we noted in our comments on our theorem B. It is its division into the suggested “deductive” and “nondeductive” or (loosely speaking) inductive components (and particularly, the interpretation of the letter) that has given rise to our difficulties.

We are grateful to Karl Popper and David Miller for the courtesy of some private exchange of opinions.

The form of maps in the brain

SIR—Further to Professor Ettlinger's pertinent comments on flying fox somatotomy¹, may I suggest that, if we accept the approach of metric tensor modelling for cortex as well as cerebellum², there would seem to be no requirement for any particular coordinate reference frame, provided that the sensorimotor connections to the central nervous system always preserve the tensorial relationships. Admittedly, my personal interpretation of the metric tensor model leaves me asking why we (and presumably some other vertebrates) need to construct a cartesian four-dimensional space-time at all.

Practical Analytical Electron Microscopy in Materials Science

1984. VII, 153 pages with 147 figures and 18 tables.
Hardcover. DM 120.-/\$ 34.95. ISBN 3-527-26224-5

High-voltage electron beams striking thin specimens in the electron microscope produce many signals. Recent development of methods for detecting and quantifying these signals transformed the technique of transmission electron microscopy (TEM) to analytical electron microscopy (AEM).

This book describes the potential and presents examples for the application of AEM, compares this method with other electron microscope procedures such as TEM and scanning electron microscopy and shows the limitations of the AEM technique. Current and potential users gain a reliable impression of the advances made possible by the exploitation of analytical electron microscopy:

1. the characterization of small particles, either isolated or enclosed in a matrix,
2. the investigation of monolayer-type segregation effects,
3. the identification of small phases and observation of microsegregation effects in multi-component materials, and
4. analyses of the microstructure and microchemistry of beam sensitive materials such as polymers.

Explanations of theoretical fundamentals, detailed practical hints and numerous references at the end of each chapter make this book a comprehensive introduction to analytical electron microscopy.

PROCEEDINGS OF THE 16TH FEBS CONGRESS

Edited by Yu. A. Ovchinnikov

The 16th Meeting of the Federation of European Biochemical Societies (FEBS) was held in Moscow in June 1984. The scientific programme was wide in scope with all contributions being of an excellent scientific quality. The Proceedings, which are published in three parts, contain over 170 papers considered to be of particular interest. These report the latest achievements in each particular branch of the science.

Part A

Symposia

- I Mechanism of enzyme action
- II Regulation of metabolism
- III Medical biochemistry
- IV Biochemistry of cell contact interactions
- V Biochemistry of viruses
- VI Biochemistry of nitrogen fixation and nitrogen assimilation in plants
- VII Evolutionary biochemistry

Contains 56 papers

July 1985; 90-6764-045-X
vi + 511 pp; DM 162

Part B

Symposia

- VIII Biochemistry of photosynthesis
- IX Genome organization
- X Protein biosynthesis
- XI Bioenergetics
- XII Molecular and enzymatic bases of carcinogenesis
- XIII Ionic channels and cellular metabolism
- XIV Structure and function of peptides and proteins
- XV Membrane organization and function

Contains 62 papers

July 1985; 90-6764-046-8
vi + 577 pp; DM 182

Part C

Symposia

- XVI Molecular bases of immune reactions
- XVII Genetic engineering
- XVIII Biotechnology
- XIX Structure and function of nucleic acids
- XX Bioorganic chemistry of low molecular bioregulators
- XXI Theoretical biochemistry

Contains 54 papers

July 1985; 90-6764-047-6
vi + 451 pp; DM 131

The books are available separately or as a set.

Approaching the past

Colin Renfrew

Archeological Explanation: The Scientific Method in Archeology.

By Patty Jo Watson, Steven A. LeBlanc and Charles L. Redman.

Columbia University Press: 1984. Pp. 309. \$26.50 (United States), \$34.50 (elsewhere).

Anthropological Archaeology.

By Guy Gibbon.

Columbia University Press: 1984. Pp. 455. \$29.50 (United States), \$38.50 (elsewhere).

ONE of the principal objectives of the "New Archaeology" of the late 1960s was to be "scientific". This meant less the use of various technical resources drawn from the natural sciences, such as radiocarbon dating or trace element analysis, than the attempt to place the reasoning behind the subject on a systematic basis.

The most persuasive of the New Archaeologists was Lewis R. Binford. Together with the first generation of his students, he sought to enlarge the scope of archaeology by asking new questions of the archaeological record, by developing techniques (such as efficient sampling strategies) which could answer specific questions once these had been clearly formulated, and by attempting to find more satisfying explanations for past events. These explanations were framed in terms of culture process: that is to say, in terms of general perceptions of the way various aspects of human societies have tended to operate. Binford and his colleagues were critical of many of the more traditional historical explanations, which were seen as frequently particularistic, tending merely to illuminate the case in question with a wealth of circumstantial detail, and often explaining the major events of the past in terms simply of the intentions of the principal actors, the Great Men of history.

The first generation of New Archaeologists emphasized the need to make explicit the bases of archaeological inference, to avoid judgements based on purely subjective assessment, and to find ways of testing hypotheses about the past, wherever possible by the use of fresh data. All of this added up to what the late David Clarke rightly termed the "loss of innocence", implying the development of a critical self-awareness of the nature of the discipline. The subject has continued to develop steadily since those early days, and has indeed met some of the hopes of those advocating an "explicitly scientific approach".

This phrase, *An Explicitly Scientific Approach*, formed the subtitle of the fore-runner of the first of the books under review, which was originally entitled *Explanation in Archeology* and published in 1971. It was an important book, seeking in a systematic way to apply the insights offered by the philosophy of science to aid archaeologists in making their subject

more scientific. This should, one might think, have been a royal road to success, but it proved instead something of a detour over philosophically shaky terrain towards rather sterile ground. The authors were open to criticism (as some reviewers indicated at the time) for following rather too readily the view propounded by the philosopher of science Carl Hempel. Hempel argued that nearly all explanation, whether in history or in the sciences, rests ultimately on the formulation of universal laws. His Deductive-Nomological (D-N) model of explanation offered an ideal to which all sciences (even historical ones) were thought to aspire.

Rather than follow this portentous mentor, the authors would have done better to ask what, in various good explanations known to them in the field of archaeology, is in fact the underlying structure of the explanation, rather than what it *ought* to be. What was clear to several archaeologists in 1971—that Hempel was an unsatisfactory guide—is clear to many philosophers of science today. Within that discipline what was once a widely accepted commonplace, the D-N model of explanation, is now seen as naive and problematic, and of much narrower application.

The present work, published 13 years later, has certainly learnt something from its initial *mésalliance* with a dogmatic philosophy of science. Different forms of Cover Law model are discussed in the first chapter, entitled "The Logic of Science, the Nature of Explanation and Archeology as Science". And happily the book moves on from these matters to talk about various aspects of archaeology in an informed and stimulating manner. Systems theory and ecology are discussed in succeeding chapters, and then the archaeological record and the design of archaeological research, and archaeological analysis, with a final chapter entitled "Archeology and Society".

Unfortunately, however, the authors have not been able to escape from the influence of Hempelian thought, and the tone of the book is firmly established in the first chapter. I find their view of science, as presented there, insensitive to the problems associated with explaining the behaviour of highly complex systems, as most living systems are. The D-N framework and statistical laws may work

well for physics, or for fields such as thermodynamics or psephology where very high numbers of unitary individuals make a probabilistic approach appropriate. But I doubt whether a molecular biologist or a meteorologist would recognize his or her science in these formulations. In fact the formal analysis of very complex systems has developed considerably in recent years, and we can begin to see that, even in the hard sciences, the trajectory of the system (that is to say its past history) as well as its present state may be relevant to its future behaviour. Fields such as catastrophe theory and the study of non-equilibrium systems are influencing archaeology as well as other sciences. The criticism to be made is therefore not necessarily the familiar one that human affairs cannot be treated scientifically, but rather that the vision of science offered here is not well developed for the explanation of the behaviour of highly complex systems.

In general, I think that the philosophy of science has served archaeology very badly over the past 10 to 15 years. The aim of being scientific, of setting explanations within an explicit framework of coherent theory, of developing a valid epistemology, is incontestably worthy. But so far most of the contributions from philosophers have been of a Procrustean inflexibility, seeking to impose on the subject under study, in this case archaeology, a series of preformulated precepts which have later themselves been shown to be of limited value. It now seems to me that to be a good philosopher of archaeology, and to produce insights into the nature of explanation in archaeology, it may pay to be a good archaeologist first.

This book, alas, continues to suffer from some of the defects of its predecessor: it tells us first how archaeology would look if it were scientific, and then tries to make the image fit. This is not only poor archaeology: it is poor philosophy of science. Perhaps it is even poor philosophy. I find it disconcerting that the first chapter, which attempts to define the nature of explanation in archaeology, and does so in terms of universal laws, offers very few examples of this kind of explanation in archaeology, and none at all which relates to human behaviour.

The book goes on to discuss several aspects of archaeology in an interesting way. It is invariably well-informed, and certainly worth reading. I share its general objectives: archaeology did need to be set on a better basis, and has benefited from the serious discussions about its nature over the past 15 years. But I am doubtful of the general validity of the view of science which is offered here.

Anthropological Archaeology is a new work which, likewise, sets out to tell us what science is, and what the philosophy of science is, before telling us very much about archaeology. It is serious, and

rather long. But although richer in examples (and illustrations) than *Archeological Explanation*, to my mind the author does not always understand his own examples very well, giving abbreviated summaries of important work which do not always catch the essence of the original. For instance I am not satisfied that the outline of the "wave of advance" model for the spread of agriculture (pp.262-265) shows how a delightfully simple dynamic formulation is derived from a very plausible set of explicit assumptions and initial conditions.

There are also some confusions, which are reflected in the glossary. "Diachronic analysis" — which implies analysis involving the passage of time and contrasts with synchronic analysis — is defined as "in the systems approach, analysis that is concerned with the mechanisms rather than the structural end products of changing subsystem relationships". This seems needlessly complicated. Survivorship curve is defined as "estimates of the percentage of individuals in subgroups of a theoretical population of 100 people that will still be alive at the end of a five year period". (Query: why specify five years?) "Tool kits" are said to be "spatial associations of archaeological materials that are assumed as a working hypothesis, to be meaningfully related to a specific task". That lacks precision, as well as clarity, and could apply as well to Stonehenge or the Pyramids of Egypt as to the subject intended.

Anthropological Archaeology does cover a number of issues seriously and thoughtfully. Its intentions, like those of *Archeological Explanation*, are thoroughly honourable. Many processual archaeologists, myself included, would share the author's aim of treating the subject in a thorough and systematic way. But this book does not convey the clarity of thought which anthropological archaeology should employ.

These two works reflect the real concern of the contemporary archaeologist to come to terms with the epistemological basis of the subject, and to develop coherent theoretical approaches. For this they will command respect. But neither they, nor the philosophers of science on whom they rely, adequately convey the lesson that different kinds of systems behave in different ways, and that complex systems can only rarely be described, and their behaviour explained, in terms of universal laws which go much beyond the obvious, the banal or the very general. The moral seems to be that the philosophy of archaeology, or of any specific science, is too important a subject to be left to the dictates of the generalist philosopher of science. □

Colin Renfrew is Disney Professor of Archaeology at the University of Cambridge, Downing Street, Cambridge CB2 3DZ, UK, and a Fellow of St John's College, Cambridge.

The shape of things to come

John D. Barrow

Mathematics and Optimal Form. By Stefan Hildebrandt and Anthony Tromba. W.H. Freeman: 1985. Pp.215. £20.95. To be available in the United States outside the Scientific American Library later this year.

WHAT do dirty washing and the design of the Great Pyramid have in common? The sort of tenuous "connection" that might generate an entire BBC television series perhaps? But there really is a connection between soap-suds and skeletons, honeycombs and Hero, the Queen of Carthage and the Olympic stadium in Munich. All are linked by the intriguing subject of optimal mathematical form, which was first discussed as a controlling factor in the natural world by D'Arcy Thompson. Here, two mathematicians who have made important contributions to the calculus of variations and minimal surfaces have produced a well-written and profusely illustrated study of the influence of extremum principles in nature.

This subject has a curious pedigree. The first modern variational principle, the so-called "Least Action Principle", was framed by Moreau de Maupertuis in 1744, although "minimum" principles had been employed by Hero to demonstrate the law of optical reflection nearly 1,700 years earlier. Maupertuis was influenced by Leibniz's doctrine of the "best of all possible worlds" and sought to overcome the defect that it appeared to be a statement of comparative reference about a unique entity. How can you say the observed laws of motion are optimal when you know of no others? Maupertuis pointed out that a certain combination of mass, velocity and the distance traversed was always minimized by the actual behaviour of a dynamical system, a requirement equivalent to imposing Newton's laws of motion. Maupertuis claimed that this displayed precisely in what sense the laws governing our world were optimal, and the inferior alternative worlds were those whose laws of motion gave paths of non-minimal action. This provided the basis for his teleological interpretation of nature. He even regarded the Least Action Principle as the most powerful proof for the existence of God. (A hundred years later a few theologians tried to maintain the doctrine of special creation in the face of fossil finds by claiming that the "failed" species revealed there were the products of the paths of non-minimal action!)

Hildebrandt and Tromba include much of the history of the calculus of variations and the appearance of optimization problems in the ancient world, for example the challenge to Dido of Carthage that she

could colonize only the area of land enclosed by the skin of an ox. Having split the skin into the thinnest strips possible, what is the optimal shape to enclose? The core of the book explains aspects of mathematical research into minimal surfaces and a variety of optimization problems involving processes occurring on unusual geometries and topologies. The results are illustrated by examples from biology, architecture, foams and bubbles, fluid flow and crystallography. Even professional mathematicians will find much that is new to them in these chapters — besides providing grist for popular lectures, they might provoke inclusion of options on the rigorous theory that underlies the subject in undergraduate mathematics courses.

Physicists will detect several absent topics that deserved inclusion in a book of this type. For example the discussion of geodesics in general relativity is too brief to be useful and misses the key contrast between Euclidean space and Minkowski's space-time: in Minkowski space-time there exists a longest world-line joining any two points, but no shortest one. The opposite is true in Euclidean space.

Altogether this is a most enjoyable book — a beautiful illustration of the interplay between mathematics and the natural world, interestingly and carefully written. □

John D. Barrow is a Lecturer in Astronomy at the University of Sussex, Brighton BN1 9QH, UK.

Spirits of Victorian England

Ivor Grattan-Guinness

The Other World: Spiritualism and Psychical Research in England, 1850–1914. By Janet Oppenheim. Cambridge University Press: 1985. Pp.503. £25, \$44.50.

ENGLISH Victorian thought continues to fascinate historians, not only for the quantity and quality of the work achieved but also for the range and complexity of philosophical positions attendant upon it. Not for them the quick lazy positivism of our modern science: this was natural philosophy, the study of nature in all her physical manifestations, and with the ontological and religious aspects set in place. One feature of these endeavours was the prominence accorded to study of the mind

and its means of communication, both in orthodox contexts and in the realms of "spiritual" activity. "The word *spiritual* is one of the most difficult and important terms in nineteenth-century thought", wrote F.M. Turner in his *Between Science and Religion: The Reaction to Scientific Naturalism in late Victorian England* (1974), and various historians have recently developed this theme in the context of psychical research, especially B. Inglis in *Natural and Supernatural* (1977). Now we have the best study to date.

Janet Oppenheim, a young American scholar about whom the publisher tells us nothing, has ransacked the publications of the period, a wide range of manuscript collections and the relevant secondary literature to produce not only another account of the rise of psychical research in the late nineteenth century but also a detailed statement on the varieties and place of spiritualism during that period. Her book falls into three parts. "The Setting" describes in two short chapters the activi-

ties of various mediums and the wide spread of spiritualist publications and societies in England at that time. "A Surrogate Faith" explains with great lucidity the plurality of positions embraced by spiritualism — the survival of spirit after death was the common assumption, but a wide range of views was adopted by different groups — and then the complicated relations between spiritualists, the principal workers within the Society for Psychical Research (SPR), which was founded in 1882, and theosophists. After a welcome suite of portraits and illustrations, there then comes the excellent third part, unhappily entitled "A Pseudoscience", in which the places of psychical research and spiritualism are described for three areas of science: in turn, psychology and phrenology (the latter a special *Scottish* interest, as the author might have pondered); evolution and medicine; and physics.

Four hundred pages of beautifully composed text are followed by 90 pages of end-notes, full of interesting information and references; however, they lack proper cross-references, so that it can be hard to find the full details of an item.

The richness and complications of Victorian thought cannot be fully conveyed in a review, although the figure (see left) and its attendant commentary include some further explanation. I focus, therefore, on the last part of the book, which is of most interest to scientists today. Sensibly, Oppenheim chooses to present the variety of positions by describing *seriatim* the views of major figures concerning spiritualism, religion, psychical research and their specialist areas of knowledge: wholehearted spiritualists such as Alfred Russel Wallace and William Crookes; men of a more cautious or vacillatory stance, such as G. J. Romanes, J. J. Thomson and Oliver Lodge; and those typified by Henry Sidgwick and his wife Eleanor, who could not subscribe to any established religious position (and in their cases also became opposed to spiritualism). The only group omitted from the survey are logicians, which is a pity, since at that time logic and psychology were closely linked. Augustus de Morgan and his wife are mentioned, but they lack the company of Mrs Boole, propounder of her late husband's algebra and also founder council member of the SPR; Lewis Carroll and John Venn; and W. E. Johnson, brother and mathematical assistant to the first research officer of the SPR, Alice Johnson.

The intertwining of the study of nature, the belief in survival and the pursuit of the paranormal that characterized a large part of Victorian thought is re-created in this book to an extent not previously achieved by an historian. Oppenheim has produced an altogether superior study. □

Ivor Grattan-Guinness is a council member of the Society for Psychical Research, 1 Adam & Eve Mews, London W8 6UG, UK.

REPRESENTATION of the spectrum of philosophical positions adopted by Victorians on religious and scientific questions. The boxes are placed on separate lines merely for convenience: the linear form adopted is a considerable over-simplification (so that, for

example, theosophy cannot fairly be indicated on it), but it conveys some impression of the distinctions and overlaps. "Naturalism" was a term used at the time to describe views which usually preferred Nature to God, facts to belief, reason to faith, and

matter to spirit. To one side lies "psychical research", referring to views normally held by leaders of the SPR (which, however, held no *corporate* opinion); to the other is "parapsychology", used in the narrow sense to refer to the experimental, laboratory-orientated studies associated from the 1930s on with J. B. Rhine and his followers. The linear diagram, then, also has a chronological overtone, from left to right. For further details see *Research in Parapsychology* 1982 pp. 283–304 (Scarecrow Press, Metuchen, NJ, 1983).

Elements of disaster

John B. Whittow

Volcanic Hazards: A Sourcebook on the Effects of Eruptions. By R.J. Blong. Academic: 1984. Pp.424. \$66, £49.50.

IN A period when such environmental disasters as drought in Ethiopia and flood in Bangladesh make headline news, it has now been generally acknowledged that many Third World communities have become so "marginalized" that the slightest aberration in their local atmospheric or geophysical systems may trigger a disaster. Records suggest that there has been no increase in either the magnitude or the periodicity of hazardous events, but death tolls continue to rise.

Bare statistics disguise a significant trend, however, for while the loss of life from natural disasters has increased in the developing world, deaths in the developed world have fallen. Most observers claim that the dichotomy results from the "technological cushion" enjoyed by developed nations, where scientific knowledge, organized planning and advanced warning systems have combined to alleviate the threat and ease the impact of natural hazards. Critics highlight the distinction between those societies which can choose from a long list of structural and non-structural adjustments and those which have no choice. The latter have limited expertise and local infrastructure, little or no opportunity to insure against disaster, and even if warnings could be disseminated the lack of mobility inhibits evacuation: they must bear the loss of life and property.

Any new publication dealing with natural hazards must be viewed in this light. Increasingly, the value of such books is judged by the degree to which they offer to help reduce the vulnerability of threatened populations, whatever their economic or social status; it is no longer enough simply to catalogue and explain the physical phenomena of natural hazards. One is encouraged, therefore, to discover that *Volcanic Hazards* has this humanitarian concern as one of its three aims. Its other objectives, of chronicling and analysing the effects of the hazard, follow the traditional approaches adopted by the plethora of books on the subject which have appeared over the past decade.

Volcanic hazard research has progressed far beyond such pioneering works as Symons and Lacroix who, respectively, described the famous eruptions of Krakatau and Mont Pelée almost a century ago. Even the modern global syntheses of Bullard¹ and Francis² have rapidly

been overtaken as earth scientists have become more concerned with effects than with causes. Following the valuable work of Walker³ on volcanic prediction, and of Sheets and Grayson⁴, who examined the relationship between volcanoes and human ecology, there has been an urgent need for a single volume that would bring together the mass of literature on volcanic eruptions in a clear and concise form. R.J. Blong has provided such a volume. Here is a well-written "sourcebook" (the author's own subtitle) which not only examines all of the well-chronicled volcanic events from Santorini (1500 BC) to Mount St Helens (AD 1980), but also provides, at the end of each chapter, an appraisal of the impact of volcanic activity on various aspects of the environment.

In Blong's assessment of deaths and injuries caused by volcanic eruptions, several points emerge. For instance,

activity have resulted from starvation and disease. It is a pity, therefore, that while the devastating effects of tephra falls, pyroclastic flows etc. on crops and livestock are critically discussed at local scales, Blong says virtually nothing about the influence of volcanic dust veils on world climates and thus on harvests. Unfortunately, he believes the topic to be beyond the scope of his book.

There are no such omissions in the sections dealing with the impact of volcanic eruptions on buildings, public utilities, communications and economic activity. When it comes to property losses we discover, not surprisingly, that it is the developed world that has borne the brunt. Almost half of the book is devoted to an analysis of the effects on the built environment, and although worldwide case studies are included Blong relies heavily on the Mount St Helens disaster.

Destruction by volcano — *The Last Days of Pompeii*, by Brüllov.

deaths due to volcanic activity are contrasted with those resulting from other natural hazards and it is shown, for example, that the victims of earthquakes outnumber volcanic fatalities by a ratio of 12:1. Of even greater note are the figures indicating that Indonesia suffers no less than 67.3 per cent of the world's volcanic casualties, compared to a combined total for New Zealand and the Mediterranean countries of 2 per cent, despite the fact that all three regions are together regarded as the most volcanically active in the world. The statistics can, of course, be explained in part by the respective population densities of the three areas. But when a developed country such as Japan (just as over-crowded as Indonesia) is taken into account, one has to conclude that Japan's 8 per cent of the total casualties must be explained by its "technological cushion" and its reduced vulnerability to hazard-induced crop losses and subsequent famine. Indeed, in the context of food shortages in the Third World, the chapter dealing with volcanic effects on agriculture is of great importance, in particular because, as Blong shows, since 1600 some 40 per cent of deaths from volcanic

This is a welcome synthesis of information on the 1980 eruption, and one which puts the economic effects in their true perspective. We learn, for example, that local employment actually increased and that the economic impact was less than that of the Boeing recession. One suspects that were it not for the mass of volcanic perception studies generated by Mount St Helens, the valuable chapter on social aspects of eruptions would never have appeared. Like other hazard perception studies, it illustrates the impossibility of producing a regional disaster plan without knowing something of the likely behavioural responses of decision makers as well as of those at risk. Without such knowledge disaster relief funding, evacuation plans and survival rates are difficult to assess.

Because it offers broad outlines for risk assessment, *Volcanic Hazards* will be invaluable to administrators, engineers and planners in developing and developed societies, as well as appealing to all earth scientists concerned with volcano monitoring and hazard delineation. A careful balance has been maintained in the treatment of man-environment relationships, the examples are well-researched, clearly explained and superbly referenced, and the whole is supported by many high-quality photographs, maps, diagrams and tables. This is an elegant volume which satisfies a longstanding need in the literature of natural hazards.

Genetic Approaches to Microbial Pathogenicity

Editor **W. Goebel**

1985 47 figures Approx 310 pages (Current Topics in Microbiology and Immunology, Volume 118) Hard cover DM 160,- ISBN 3-540-15597-X

This volume contains a representative collection of studies into virulence properties from Gram-positive and Gram-negative bacteria where modern genetic techniques have been successfully applied. The examples described include important bacterial toxins (for instance diphtheria toxin, cholera toxin, toxic shock syndrome toxin, and hemolysins), adhesion structures from *Escherichia coli* and *Neisseria gonorrhoeae*, and other properties, such as iron uptake systems, serum resistance and invasion factors, that influence bacterial pathogenicity. The volume gives an account not only of the present state, but also of possible future developments of these systems

Announcing a New Series:

Progress in Clinical Biochemistry and Medicine

Editors **E. Beaulieu, D. T. Forman, L. Jaenicke, J. A. Kellen, Y. Nagai, G. F. Springer, L. Trager, J. L. Wittliff**

Scientific progress makes it increasingly possible to relate disease to irregularities on a molecular level

Both diagnosis and cure can be targeted to a well defined biological structure. Modern medical research can now devote its attention to the investigation of the interaction of molecules and bio-macromolecules, formerly the area of chemistry, biochemistry and pharmacology

This series provides a vehicle for the dissemination of results in a multidisciplinary area of contemporary research. It will publish extensive high-level review articles relating a particular subject to the activities of medical chemistry, making specialized information and useful references available to important groups of scholars

Volume 1

Essential and Non-Essential Metals Metabolites with Antibiotic Activity Pharmacology of Benzodiazepines Interferon Gamma Research

1984 42 figures VII, 203 pages Hard cover DM 98,- ISBN 3-540-13605-3

Contents: *M. Costa*, *A. J. Kiaker*, *S. R. Pateino* Toxicity and Carcinogenicity of Essential and Non-Essential Metals - *R. G. THEORY AND PRACTICE OF SCANNING OPTICAL MICROSCOPY

T. Wilson and C. J. R. Sheppard

1984, 224pp., \$39.50/£25.00 (UK only), ISBN 0 12 757760 2

This book presents a self-contained account of the major theoretical aspects of scanning optical microscopy. Practical applications of semiconductor and integrated circuit studies are emphasized. No previous knowledge of Fourier optics is assumed, and Fourier imaging theory is explained from first principles. Particular attention is given to the confocal optical arrangement and the optical beam induced contrast mode is discussed in detail. The contents of this book combine to give a complete review of the subject and the 150 illustrations and micrographs further enhance the accessibility of this volume.

PHOTOGRAPHY FOR THE SCIENTIST

Second Edition

Superfluidity in neutron stars

David Pines & M. Ali Alpar*

Department of Physics, University of Illinois at Urbana-Champaign, 1110 W Green, Urbana, Illinois 61801, USA

Recent developments have radically changed our understanding of the dynamics of neutron-star superfluids. We review astrophysical evidence for the existence of at least three distinct superfluids inside neutron stars from the observed relaxation of the rotation and spin-down rates of the pulsars Vela, Crab and PSR0525+21, following sudden jumps (glitches) in these quantities. We also discuss the effects of the superfluid interior in the accreting neutron-star X-ray sources.

SUPERFLUIDITY in neutron stars was first suggested^{1,2} before the observation of such stars; the suggestions were as remarkably prescient as the first theoretical proposals of the existence of neutron stars and pulsars³⁻⁵. The discovery of radio pulsars and accreting X-ray sources placed neutron stars firmly in the realm of observational astrophysics. Subsequent accumulation of timing data revealed that radio pulsars experience sudden period changes ('glitches'), and their relaxation following such a glitch is too slow to be explained in terms of the viscous processes of normal matter. These timing observations provided the evidence for the presence of cosmic superfluidity and motivated the theoretical work on the rotational properties of this superfluid⁶. As is well known from laboratory experiments, the rotational state of a superfluid is determined by a distribution of quantized vortex lines, just as in a hard superconductor the magnetic field configuration is determined by a distribution of quantized flux lines. The motion of these vortex (or flux) lines is governed by their interactions with normal matter, including the possible pinning of the vortex lines to preferred sites in an inhomogeneous medium, a phenomenon well known in studies of hard superconductivity. The subject of this review is the fascinating extension of these basic concepts of superfluidity to the largest superfluid systems encountered in nature, neutron stars. Several physical effects peculiar to the dense state of matter in neutron stars play a key role in this extension.

The salient features of the current picture are that: (1) the core superfluid, which comprises the bulk of the moment of inertia, rotates rigidly with the crust of the star despite being in the superfluid state; (2) because of vortex pinning the crust superfluid, which contributes $\sim 10^{-2}$ of the star's total moment of inertia, can be out of equilibrium with the observed crust for timescales of weeks, months and years, and is responsible for a variety of interesting timing behaviour, primarily pulsar glitches and post-glitch relaxation; and (3) the observed post-glitch relaxation times provide a means of estimating the interior temperature of pulsars.

Structure of neutron stars

The details of neutron-star structure are quite sensitive to the still imperfectly understood neutron matter equation of state at densities greater than $\rho_0 \approx 2.8 \times 10^{14} \text{ g cm}^{-3}$, the density of nuclear matter⁷. If the basic hadron equation of state is comparatively stiff (see ref. 8 for a recent review), the cross-section of such a star would be that shown in Fig. 1. Beneath an atmosphere only a few metres thick one finds an outer crust, 0.5-km thick, of increasing density ($7 \times 10^6 \text{ g cm}^{-3} \leq \rho \leq 4 \times 10^{11} \text{ g cm}^{-3}$), containing a solid array of nuclei and a highly degenerate relativistic electron plasma⁹. The inner crust begins at $\rho \sim 4.3 \times 10^{11} \text{ g cm}^{-3}$ and extends a few km until a mass density $\rho \sim 2.4 \times 10^{14} \text{ g cm}^{-3}$

is reached. It contains a highly degenerate superfluid neutron liquid as well as the lattice of increasingly neutron-rich nuclei and relativistic electrons. The quantum liquid interior of the star is expected to consist mainly of superfluid neutrons, with an admixture of a few per cent of superconducting protons and normal electrons. The constituents of neutron stars at densities well in excess of ρ_0 are uncertain (see ref. 10 for a review of some of the possibilities). It is possible that at densities a few times ρ_0 one may find an alternating layer structure involving a pion condensate^{11,12}. Quark matter is not expected¹⁰ because the maximum central densities of neutron stars ($\leq 5\rho_0$) are rather less than those at which such a state would be favoured. Because of the very high thermal conductivity of degenerate matter, the temperature, T , of the star is quite uniform, and is typically $\sim 5 \times 10^8 \text{ K}$ for a young neutron star such as the Crab pulsar. This would seem at first sight to be high, until one realizes that, because of the extraordinarily high densities involved, typical crustal melting temperatures are $\sim 10^{10} \text{ K}$ (1 MeV), whereas degeneracy temperatures for the quantum liquid constituents are still higher (5–50 MeV) and energy gaps for the neutron and proton superfluids may represent an appreciable fraction of their degeneracy temperatures. The crustal material thus resembles terrestrial solids in the liquid helium range, whereas the quantum liquids resemble liquid He in the millidegree range.

Neutron superfluids

The effective interaction between two neutrons is a combination of a strong short-range repulsion and a long-range attraction. At least two distinct pairing states of neutron superfluids are expected: (1) in the inner part of the crust, where the interparticle spacing is greater than the range of the repulsive forces ($\sim 10^{-13} \text{ cm}$), $^1\text{S}_0$ pairing dominates¹³⁻¹⁵. (2) at the higher densities ($\geq \rho_0$) characteristic of the quantum liquid interior, the combination of short-range repulsion and an attractive tensor force leads to a $^3\text{P}_2$ paired superfluid^{13,16}. The transition temperatures are shown in Fig. 2 as a function of density in the star.

Because neutron stars rotate, neither neutron superfluid will be spatially uniform; both contain an array of vortex lines parallel to the rotation axis, of sufficient number that on a macroscopic scale the neutrons will seem to be rotating as a rigid body. As the circulation per vortex is $\kappa = h/2m_n$, the density of vortices per unit area is $2m_n\Omega/\pi\hbar$ to mimic rigid-body rotation (where $\hbar$ is Planck's constant, m_n is the neutron mass, and Ω is the rotation frequency). This vortex density is $\sim 2 \times 10^5 \text{ cm}^{-2}$ for the Crab pulsar ($\Omega \approx 191 \text{ s}^{-1}$).

In the stellar crust, the normal cores of the vortices where the condensate wavefunction decreases to zero either may be pinned to the lattice of nuclei present there or may thread the spaces between them. Because the nuclei also contain superfluid neutrons, whether or not pinning occurs is a matter of comparative superfluid energetics. It is favourable for a vortex line to

* Present address. TBTAk, Research Institute for Basic Sciences, Gebze-Kocaeli, Turkey

pin to a nucleus if the energy cost per particle to create its normal core, $\sim \Delta^2/E_F$, where Δ is the energy gap for superfluid neutrons and E_F their Fermi energy, is thereby reduced⁶. More precisely, the pinning energy per nucleus is^{17,18}

$$E_p = \frac{3}{8} \left[\frac{\rho_{\text{out}} \Delta_{\text{out}}^2}{(E_F)_{\text{out}}} - \frac{\rho_{\text{in}} \Delta_{\text{in}}^2}{(E_F)_{\text{in}}} \right] V \quad (1)$$

Here 'out' and 'in' denote local values of Δ and E_F for superfluid neutrons outside and inside the nuclei, V is the overlap volume of the vortex core and the nucleus of radius R_N ; the core radius is the coherence length of the outside neutron superfluid,

$$\xi = 2E_F / \pi k_F \Delta \quad (2)$$

Calculations^{15,19} suggest that the pinning layers, in which it is energetically favourable for vortex lines to go through the nuclei, extend from densities $\sim 10^{13}$ to $\sim 2 \times 10^{14} \text{ g cm}^{-3}$. With a pinning energy E_p , the maximum available pinning force per unit length of vortex line is

$$f_p = \frac{E_p(\rho)}{\xi(\rho)b(\rho)} \quad (3)$$

where ρ is the average density characterizing the pinning layer and b is the spacing between successive pinning centres along the vortex line.

The pinning energy and coherence length are determined by the equilibrium nuclear configuration²⁰ and the superfluid energy gap, while the distance between pinning centres depends on the physical circumstances under which pinning takes place. Pinning will be maximal in the strong pinning layers, where E_p is greater than a typical lattice energy, $E_L \sim Z^2 e^2 R_N / b_z$ (b_z is the lattice spacing), so that the pinning force is strong enough to dislodge nuclei from their equilibrium sites in the lattice, and b is comparable with b_z . The transition to weak pinning layers occurs when $E_p \leq E_L$. In the weak pinning layers, the vortex core pins only to those sites through which it passes; the spacing between pinning sites, b , is $\sim (E_L/E_p)b_z$, and the effective pinning energy is reduced to $\sim E_p(E_p/E_L)$ (ref. 18). Finally, where the coherence length, $\xi \geq b_z$, a vortex core can 'pin' to more than one nucleus at a time. Under these circumstances, which are expected in the higher-density regions of the pinning layers, moving a vortex line requires still less change in the pinning energy; one is in a region of superweak pinning¹⁹, in which the effective spacing, b , between multiple pinning sites is far larger than $(E_L/E_p)b_z$.

The proton superfluid

The basic interaction between isolated protons resembles that for neutrons, whereas the density of the proton liquid in the stellar core is some two orders of magnitude smaller than that of the neutron liquid; hence the interior proton liquid will superconduct in a $^1S_0$ pairing state²¹.

Because the critical field, $H_{ci} \geq 10^{15} \text{ G}$, is enormous compared with the field strengths $\sim 10^{12} \text{ G}$ that are found in pulsars, one might expect that the proton superconductivity would have a dramatic effect on the magnetic properties of the neutron star, through expulsion of the flux from the superconducting regions. It does not, because the electrical conductivity, σ , of the normal state is so large that the characteristic time for flux expulsion from macroscopic regions is typically $\gg 10^8 \text{ yr}$ as Baym, Pethick and Pines²² have shown. As the star cools, superconductivity nucleates with the magnetic field present. The London penetration depth is greater than the proton coherence length, so that the flux penetrates the superfluid region in a vortex state similar to that found in laboratory type II superconductors for $B > H_{ci}$.

Core neutron communication

The principal energy source of a pulsar is the rotational energy of the neutrons. How do the core neutrons, which make up the bulk of the neutron star, follow changes in the rotational state of the crust? Consider first the charged particles. The electrons and protons in the interior must co-rotate by electromagnetic

Fig. 1 Cross-section of a $1.4 M_{\odot}$ neutron star, calculated using the Bethe-Johnson equation of state.

coupling, irrespective of whether or not the protons are superfluid (any appreciable differential rotation would give rise to inordinately large magnetic fields). The charged particles in the crust and those in the interior communicate readily through the viscosity of the electrons and/or the magnetic field in the interior. Easson²³ finds that the core plasma responds to sudden changes in the crustal angular velocity with a magnetic spin-up time $\sim 10 \text{ s}$. The Ekman time for electrons is of the same order^{23,24}.

The rotational state of the neutron superfluid is determined by the distribution of its quantized vortices. Any change in the rotation rate of the crust is communicated to neutron vortex cores via electrons and protons. Thus, the dynamical coupling time of the neutron superfluid is determined by the timescale for the scattering of electrons against the normal cores of superfluid neutron vortices. For electron-neutron magnetic moment scattering, the charged particle-neutron coupling time is found to be $\sim 10^7 \text{ s}$. These considerations led to the conclusion that if both the neutrons and the protons in the stellar interior are superfluid, the relaxation time which characterizes the coupling between the crust and the interior superfluid neutrons is a macroscopic time, of the order of years²². This formed the basis for the proposal of the two-component model of crust-core coupling in neutron stars²⁵. More recent work^{26,27} has shown that there are mechanisms of intrinsic magnetization of the neutron vortices that result in a much stronger coupling of the neutron superfluid to the charged particles and to the crust.

Glitches and post-glitch relaxation

The inner part of the pulsar magnetosphere adjacent to the neutron star crust rotates with it. Thus, the observed pulse timing reflects the rotational behaviour of the crust. Sudden increases in rotation rate, termed glitches, have been observed from many pulsars. The Crab pulsar has had two prominent glitches²⁸ with $\Delta\Omega/\Omega \sim 10^{-8}$ – 10^{-9} . The old pulsar 0525+21 has exhibited a glitch of similar magnitude²⁹. The Vela pulsar has had six glitches^{30–32} with $\Delta\Omega/\Omega \sim 10^{-6}$ since 1969, and each of the pulsars 1641–45, 1325–43 and 2224+65 have shown one such giant glitch^{33–35}. The statistics of the Vela-type giant glitches is consistent with the hypothesis that all pulsars have them, although glitches become less frequent as pulsars evolve³⁶.

Fig. 2 Calculated superfluid transition temperature as a function of baryon density for neutrons and protons¹⁰. Dashed curves indicate extrapolations to lower densities

Glitches are sudden in the sense that observationally their rise time seems to be less than a day. By contrast, the post-glitch relaxation in the timing behaviour of a pulsar, which has been observed in the Crab, Vela and PSR0525+21, has timescales from a few days to years.

Post-glitch relaxation is determined by the coupling of the crust to the superfluid neutrons. Let us write the torque acting on the crust of a neutron star rotating at angular velocity, Ω_c , as

$$I_c \dot{\Omega}_c = N_{\text{ext}} - N_{\text{int}} \quad (4)$$

I_c is the moment of inertia of the crustal lattice plus whatever other stellar material is rigidly coupled to it, N_{ext} is the external torque acting on the star and N_{int} describes the coupling of the crust to those superfluid neutrons that couple to it on observable timescales. In the two-component model of Baym *et al.*²⁵, the internal torque is ascribed to the core neutron superfluid of inertial moment I_s and angular velocity $\Omega(t)$, and is assumed to take the form

$$N_{\text{int}} \equiv I_s \dot{\Omega} = (I_c/I) (\Omega_c - \Omega)/\tau_c \quad (5)$$

characteristic of simple mutual friction between the crust and core (where I is the total moment of inertia and τ_c is a crust-core coupling time). After a sudden initial jump $(\Delta\Omega_c)_0$ in Ω_c , the post-glitch behaviour described by equations (4) and (5) is

$$\Omega_c(t) = \Omega_0(t) + (\Delta\Omega_c)_0 [Qe^{-t/\tau} + (1-Q)] \quad (6)$$

where $\Omega_0(t)$ is the extrapolated frequency in the absence of the glitch, $\tau = \tau_c(I_s/I)$ and $Q \approx I_s/I$. The two-component theory provided a good fit to the initial post-glitch data from the Crab and Vela pulsars. For both pulsars, however, the Q and τ values required to obtain a fit differed somewhat from one glitch to the next. Moreover, Boynton and Deeter³⁷ showed that one could not fit the noise in the timing data on the Crab pulsar using those Q and τ values which had provided a satisfactory explanation of the larger Crab glitches, while data accumulation and the detailed analysis by Downs³⁰ of the post-glitch behaviour of the Vela pulsar following its four glitches, and by Lohsen²⁸ and Demianski and Proszynski³⁸ of the Crab pulsar following its two major glitches, provided a wealth of new data for which the simple two-component model could not provide an adequate explanation.

The physical origin of the giant glitches in the Vela pulsar posed an even greater puzzle: starquake theory⁹, although plausible for the Crab pulsar glitches³⁹, could not explain the magnitude and frequency of the Vela glitches. The most promising alternative which emerged was the idea of a sudden catastrophic unpinning of the pinned vortex lines in the crustal neutron superfluid every few years as a result of pulsar spin-down^{40,41}. In the course of exploring the behaviour of the pinned superfluid

between giant glitches, it was concluded that not only could the pinned superfluid be responsible for the giant glitches, but that the entire dynamics of post-glitch behaviour was probably related to the pinned superfluid; in other words, the post-glitch behaviour was the response of the pinned crustal neutron superfluid to a glitch, and physical processes must exist which couple the core neutron superfluid rapidly (on timescales $\leq$ days) to the crust^{18,42}. Thus, a general theory of the coupling between the pinned superfluid and the crust, which occurs by vortex creep (the motion of the pinned vortex lines in response to changes in the crustal rotation frequency⁴³), was developed. A detailed re-examination of the coupling between the crust and the core neutron superfluid was carried out^{26,27} in which additional physical mechanisms which couple the core neutrons rapidly to the crust were discovered, while the vortex creep theory was found not only to provide an excellent fit^{19,44} to the timing data^{28-30,38}, but to offer the possibility of determining the internal temperature of pulsars.

Neutron star coupling

Sauls, Stein and Serene²⁶ considered the structure of the vortices in the $^3P_2$ pairing state in the neutron superfluid core. They found that because of the small spontaneous magnetization that appears in the region near the vortex core, the coupling is qualitatively different from the relaxation mechanism considered by Feibelman⁴⁵, who calculated the scattering of electrons by magnetic moments of neutrons in low-lying excited states in the core of the vortex line. This requires thermal excitations and yields a relaxation time which is $\sim \exp(\Delta^2/k_B T E_F)$ (where k_B is Boltzmann's constant), whereas the electron magnetic vortex relaxation time is comparatively insensitive to the gap and temperature, going as the inverse power of $\Delta(T)$; the latter process gives relaxation times of about a year.

Alpar, Langer and Sauls²⁷ have examined the change in the structure of a neutron vortex line that results from the interaction between the neutron and proton condensates in the quantum liquid interior. Superfluid drag induces a proton charge current around each neutron vortex giving rise to a magnetic field confined within a screening radius ~ 50 fm, but of magnitude $\sim 10^{15}$ G, far larger than the spontaneous magnetization discussed above. The resulting charge-vortex line relaxation time is also insensitive to temperature and is $\tau_v \approx 20 P(s)$, where P is the rotation period. The dynamical coupling time of the core superfluid is

$$\tau \approx \frac{\tau_v}{x} \approx 400 P(s) \quad (7)$$

where $x \approx 0.05$ is the charged fraction of the neutron star core. This work provides crucial support for invoking only the crust superfluid in a model of pulsar glitches and post-glitch relaxation, which we now consider.

Vortex creep theory

The coupling between the pinned crustal superfluid and the crust is achieved by thermal creep of the vortex lines against pinning energy barriers, by analogy with flux creep in type II superconductors^{46,47}. In the steady state the pinned superfluid is coupled to the rest of the star and shares the effect of external torques. A glitch perturbs vortex creep away from its steady-state rate. Part of the pinned superfluid is thereby decoupled, and its gradual recoupling leads to observable behaviour. The sudden change in $\dot{\Omega}_c$ which accompanies the glitch is associated with sudden decoupling of the pinned superfluid region with an effective moment of inertia $\bar{I}_p$,

$$\bar{I}_p/I \equiv (\Delta\dot{\Omega}_c/\dot{\Omega}_c)_0 \quad (8)$$

and conservation of angular momentum gives

$$\bar{I}_p \delta\bar{\Omega}_p = I_c \Delta\Omega_c \quad (9)$$

where $\delta\bar{\Omega}_p$ is the mean decrease of the superfluid rotation rate and $\Delta\Omega_c$ is the magnitude of the glitch.

The angular velocity of the neutron superfluid is determined by the distribution of the pinned vortex lines. With azimuthal symmetry, the value of $\Omega(r) \equiv v(r)/r$ (where r is the cylindrical distance from the axis of rotation) is determined by the usual superfluid equations relating the macroscopic rotation rate to the distribution of quantized vortices:

$$\int_0^r (\nabla \times \mathbf{v}) \cdot d\mathbf{S} = \oint \mathbf{v} \cdot d\mathbf{l} = 2\pi\Omega(r)r^2$$

$$= \kappa \int_0^r 2\pi r' n(r') dr' \quad (10)$$

while vortex conservation leads to

$$\dot{\Omega} = -\kappa \frac{nv_r}{r} \quad (11)$$

Here, $n(r)$ is the number of vortices per unit area, $\mathbf{v}$ is the superfluid velocity, and v_r is the radial velocity of the vortex lines. From these equations it follows that $\Omega(r)$ can change only if vortices move. Their motion is described by an internal torque,

$$N_{\text{int}} \equiv \int_p dI_p \dot{\Omega}(r, t) \quad (12)$$

while the rate at which thermally activated vortex lines are able to tunnel between adjacent pinning configurations is

$$v_r = v_0 \exp \left[-\frac{E_p (\omega_{\text{cr}} - \omega)}{k_B T \omega_{\text{cr}}} \right] \quad (13)$$

where T is the crustal temperature, $\omega \equiv \Omega - \Omega_c$ is the superfluid angular velocity relative to that of the crust, and

$$\omega_{\text{cr}} \equiv (\Omega - \Omega_c)_{\text{max}} = \frac{f_p}{\rho \kappa r} \equiv \frac{E_p(\rho)}{\rho \kappa r \xi b} \quad (14)$$

is the maximum superfluid lag which can be supported by the pinning force, defined in equation (3). The approach to steady state is characterized by a relaxation time, τ_i , proportional to the temperature⁴³,

$$\tau_i = \left(\frac{\omega_{\text{cr}}}{E_p} \right) \frac{k_B T}{|\dot{\Omega}_{\infty}|} \equiv \frac{\alpha_i T}{|\dot{\Omega}_{\infty}|} \quad (15)$$

where $\dot{\Omega}_{\infty}$ is the steady-state value of $\dot{\Omega}_c$ and $\dot{\Omega}_i$, and the subscript 'i' refers to the pinning layer in question.

Glitches are catastrophic unpinning events extraneous to the creep process which itself involves a continuous slow vortex motion. The internal torque produced by the neutron superfluid in response to a glitch, $(\Delta\Omega_c)_0$, takes the simple form

$$N_{\text{int}}(t) = \sum_i I_i \dot{\Omega}_{\infty} \frac{1}{1 + (e^{t_{oi}/\tau_i} - 1)e^{-t/\tau_i}} \quad (16)$$

where the I_i are the moments of inertia of the distinct pinning layers; the t_{oi} which appear in equation (16) are post-glitch delay times. For pinning layers where there is no glitch-associated vortex motion,

$$t_{oi} = \frac{(\Delta\Omega_c)_0}{|\dot{\Omega}_{\infty}|} \quad (17)$$

and in those regions where there is glitch-associated vortex motion,

$$t_{oi} = \frac{\delta\Omega_i}{|\dot{\Omega}_{\infty}|} = \frac{X_i \kappa}{2\pi r^2 |\dot{\Omega}_{\infty}|} \quad (18)$$

where $\delta\Omega_i$ is the glitch-associated change in the superfluid rotation frequency and X_i is the number of vortices that have moved through the region.

The vortex creep theory of post-glitch response differs from the two-component model²⁵. (1) It involves a number of distinct components which, however, make up only a comparatively small fraction (~a few per cent) of the neutron superfluid, namely the pinned superfluid in the crust. This is borne out by the observed values of $(\Delta\dot{\Omega}_c/\dot{\Omega}_c)_0 \sim 10^{-3}$ – 10^{-2} (compare with

Fig. 3 Fits to the post-glitch $\dot{\Omega}_c(t)$. a, Representative post-glitch fit for the Vela pulsar¹⁹; $\dot{\Omega}_c(t)$ following the glitch of July 1978. b, Fit to $\dot{\Omega}_c(t)$ following 1975 Crab pulsar glitch⁴⁴. c, Fit to $\dot{\Omega}_c(t)$ following the glitch observed in PSR0525+21 (ref. 44). In each case, $t=0$ denotes the epoch of the first post-glitch timing observation and $\Delta\dot{\Omega}_c(t) \equiv \dot{\Omega}_c(t) - \dot{\Omega}_c(0)$.

equation (8)). (2) It is a fundamentally nonlinear theory of superfluid response; glitch-associated vortex creep depends exponentially on the size of the glitch (in regions in which no vortex motion occurs) and on the change in the superfluid velocity (in regions in which vortex motion occurs during the glitch). (3) It leads to relaxation times proportional to the internal temperature of the star, so that timing observations can provide a unique probe of the internal stellar temperature. This internal temperature can then be used to obtain an estimate of the surface temperature.

Thermally activated vortex creep leads to an internal dissipation of the stored rotational energy of the neutron star. The magnitude of the continuous energy dissipation resulting from creep follows directly from the superfluid equations of motion, and is

$$\dot{E}_{\text{diss}} \equiv |\dot{\Omega}_c| \int_p dI_p \omega_{\infty} \equiv |\dot{\Omega}_c| I_p \bar{\omega}_{\infty} \quad (19)$$

where I_p is the moment of inertia of the entire set of pinning layers, $\bar{\omega}_{\infty}$ is an average through the pinning layers and ω_{∞} is the steady-state value of $\Omega - \Omega_c$. This dissipation is the principal source of heat for old pulsars which have radiated away their original heat content.

Vela pulsar glitches

Alpar *et al.*¹⁹ have shown that the observed complex post-glitch behaviour of the Vela pulsar following the four glitches which took place in the decade 1969–79 (ref. 30) finds a straightforward explanation in terms of vortex creep theory. They fit the observational data of Downs with the following expression for $\dot{\Omega}_c(t)$,

$$I_c \dot{\Omega}_c(t) = N_{\text{ext}} - N_1 - N_2 - N_A \quad (20)$$

Here N_1 and N_2 are specified by equations (16) and (17), with relaxation times τ_1 and τ_2 . These torques represent an average response of two distinct pinning layers through which no vortices move. A third region, through which vortices move, is represented to a first approximation by

$$N_A \approx \dot{\Omega}_\infty \frac{I_A t}{t_{OB}} \quad (21)$$

(ref. 19), where I_A is the moment of inertia of the superfluid in pinning layers (where vortices unpin and repin) and t_{OB} is the post-glitch delay time given by equation (18) on taking X_1 to be the total number of vortices that unpin. A choice of $\tau_1 = 3$ days and $\tau_2 = 60$ days, for each of the four glitches, gives an excellent fit to the observational data (Fig. 3). Alpar *et al.*¹⁹ conclude that the two distinct pinning layers correspond to weak pinning and superweak pinning respectively, characterized by $\langle \alpha^{sw} \rangle \sim 2 \times 10^{-17}$ days $K^{-1} s^{-2}$ and $\langle \alpha^w \rangle \sim 4 \times 10^{-16}$ days $K^{-1} s^{-2}$ (see equation (15)). Within each pinning region the actual pinning parameters may vary either way by factors of ~ 2 . The size of the inertial moments of these pinning regions ($\sim 10^{-2} I$) is physically reasonable, in terms of current neutron-star models.

From the observed relaxation times, Alpar *et al.*¹⁹ estimate the internal temperature of the Vela pulsar to be $(1.5 \pm 1) \times 10^7$ K. The quoted errors do not refer to a particular calculation, but rather reflect an estimate of the degree of uncertainty introduced by lack of knowledge of various pinning parameters.

Crab pulsar

Alpar, Nandkumar and Pines find, surprisingly, that the post-glitch behaviour of the Crab pulsar following its two large glitches in 1969 and 1975 could be fitted (see Fig. 3b) with the extreme (Occam's razor) hypothesis that both the internal structure and the vortex pinning sites in the Crab pulsar are essentially the same as those hypothesized for the Vela pulsar, so that the only significant physical differences between the two pulsars reside in the spin down rate and internal temperature⁴⁴. In this fashion they deduce an internal temperature for the Crab pulsar of 3.8×10^8 K, with, again, an uncertainty either way of a factor of ~ 2 . The surface temperatures of the Vela and Crab pulsars can be estimated using the scaling laws obtained by Gudmundsson *et al.*⁴⁸. For a $1.4 M_\odot$ neutron star with a reasonably stiff equation of state, one finds the surface temperatures observed at infinity are $T_{\infty, \text{Vela}} \approx 3 \times 10^5$ K and $T_{\infty, \text{Crab}} \approx 1.6 \times 10^6$ K. For both pulsars, these surface temperatures are well below the upper limits obtained by the Einstein observatory^{49,50}. Comparing our estimates with calculations on neutron star cooling and evolution (see ref. 51 for recent review), one finds that an internal temperature ratio of 25 is not consistent with the standard cooling calculations, which, for a given Crab temperature would predict a considerably hotter Vela pulsar. Therefore, these results may provide the first indication that non-standard, more rapid cooling scenarios (perhaps reflecting the presence of a pion condensate, if a pion condensate indeed leads to sufficiently rapid cooling) are in operation in neutron stars.

Old pulsars

Consider now pulsars which are old enough to have radiated away their original heat content so that their dominant source of heat is due to internal dissipation by vortex creep. On equating the rate of dissipation $\dot{E}_{\text{diss}}$ (equation (19)) to the stellar luminosity, one finds a limiting black-body surface temperature of

$$T_s \approx 1.1 \times 10^5 [I_{p,43} \bar{\omega}_{cr} \Omega_{-14} / R_6^2]^{1/4} \quad (22)$$

From the upper limit to the surface luminosity of the Vela pulsar in the soft X-ray region⁴⁹ and the Einstein detection of PSR1929+10 (ref. 52), we have estimated $I_{p,43} \bar{\omega}_{cr}$ to be ≤ 1 (ref. 53). For such a pulsar, the thermal flux given by equation (22) is small enough for the internal temperature to be close to the surface temperature. If all old pulsars possess essentially the same pinning layers as the Crab and Vela pulsars, they would have temperatures determined by internal dissipation according

to equation (22) and would possess creep relaxation times that depend only on their spin-down rate, and are

$$\tau_{sw}^{\text{old}} \sim 220 |\Omega_{-14}|^{-3/4} \text{ days} \quad (23)$$

$$\tau_w^{\text{old}} \sim 4.4 \times 10^3 |\dot{\Omega}_{-14}|^{-3/4} \text{ days} \quad (24)$$

for the superweak and weak pinning layers, respectively.

Among the old pulsars which have exhibited glitches, post-glitch timing observations are available only for PSR0525+21. Alpar, Nandkumar and Pines⁴⁴ (Fig. 3c) find that vortex creep theory provides a good fit to the observed post-glitch behaviour of this pulsar with a 'fast' relaxation time of ~ 150 days and is consistent with the additional presence of a much slower 3,000-day relaxation process. The vortex creep theory prediction of τ for PSR0525+21 is, from equation (24), some 140 days, in excellent agreement with this fit. Thus vortex creep theory can explain the post-glitch behaviour of both very young and very old pulsars. What is striking is that it does so without involving new parameters for each glitch or pulsar.

Superfluidity in millisecond pulsars

The recently discovered millisecond pulsars^{54,55} have much larger angular velocities, Ω , and much lower inferred dipolar fields, B_s , than 'ordinary' pulsars. Neither of these changes alters the superfluid physics of the neutron star⁵³. The search for observational consequences of superfluidity in millisecond pulsars thus becomes a search for pinned crustal superfluid phenomena: (1) the internal generation of heat by vortex creep; (2) macroglitches, such as those observed in the Vela pulsar, produced by the simultaneous unpinning of a large group of vortex lines; (3) post-glitch timing behaviour associated with the gradual recoupling of the pinned superfluid; (4) timing noise.

The first three phenomena scale with $\dot{\Omega}_c$, whereas the value of $|\dot{\Omega}_c|$ ($= 2.9 \times 10^{-13}$ rad s^{-2}) for the millisecond pulsar PSR1937+21 resembles that of ordinary pulsars. Our results are not encouraging for would-be observers of glitches in millisecond pulsars; although our estimated glitch intervals ($\sim 10^2$ to $\sim 10^4$ yr) are comparable with those found in the conventional pulsar sample³⁵, the present sample of millisecond pulsars is too small to make it likely that a substantial glitch in one of these will be observed in the near future.

The timing from millisecond pulsars is of great importance in view of the potential practical applications of the excellent timing accuracy⁵⁶ of PSR1937+21. To estimate the contribution of the unpinning events to timing residuals, we take the rate of unpinning events to be $R \sim |\dot{\Omega}_c| / \delta \Omega_{cr}$ where $\delta \Omega_{cr}$ is a critical lag between superfluid and crust rotation rates needed to trigger a typical unpinning event, and assume that the unpinning event involves an angular momentum transfer of order $\Delta L = I_c \Delta \Omega_c \approx I_s \delta \Omega_{cr}$ where I_s is the moment of inertia of the region through which vortices move in a typical unpinning event. The noise strength S then scales with $\dot{\Omega}_c$:

$$S \equiv R \langle \Delta \Omega_c^2 \rangle \sim |\dot{\Omega}_c| \left(\frac{I}{I_s} \right)^2 \delta \Omega_{cr} \quad (25)$$

There is some evidence⁵⁷ for a correlation of S with $|\dot{\Omega}_c|$. On scaling from the observations of white $\dot{\Omega}_c$ noise in the noisiest source, the Crab pulsar, and expressing the result as an r.m.s. timing residual⁵⁸, one has

$$\langle R^2 \rangle_{1937+21, \text{intrinsic}}^{1/2} \sim 4 \times 10^{-2} \mu s \quad (26)$$

$\sim 5\%$ of the current residual $\approx 0.9 \mu s$ (ref. 56). Thus, one can be (cautiously) optimistic that the intrinsic contributions to the noise in PSR1937+21 are quite small. Note, however, that if the events are triggered by a critical value $(\delta \Omega / \Omega)_{cr}$ instead of $\delta \Omega_{cr}$, $S \propto \dot{\Omega}_c \Omega_c$ and scaling from the Crab pulsar yields an estimate of intrinsic noise comparable with the observed residuals in PSR1937+21.

Accreting X-ray sources

We have concentrated on effects of superfluidity in radio pulsars, where the external torque can be taken to be constant on time-

scales of the observed variations in timing behaviour. In the new picture of neutron-star superfluids that we have presented, only $\sim 10^{-2}$ of the superfluid interior, the pinned superfluid in the crust, produces observable deviations from rigid-body behaviour, and the resulting Ω_c variations are of the same order. Such variations are clearly unimportant in comparison with the observed variations in the accretion torque in systems like Her X-1 or Vela X-1 (ref. 59 and F. K. Lamb *et al.*, in preparation), so that the superfluid interior is negligible as a source of timing noise in accreting X-ray pulsars.

The dynamics of the pinned superfluid does, however, place severe constraints on precession (wobble) frequencies and damping times, which in effect rule out neutron-star precession as the explanation of various quasi-regular timescales observed in X-ray binaries (for example, the 35-day cycle in Her X-1). First, Shaham⁶⁰ has pointed out that the presence of pinned superfluid leads to wobble frequencies Ω_w given by $\Omega_w/\Omega \sim I_p/I \sim 10^{-2}$, where Ω is the rotation frequency and I the total moment of inertia. Second, precession of the crust will be damped by its coupling to a fluid interior. The damping time is $\tau_d \equiv \tau\Omega/\Omega_w$ (ref. 61) where τ is the dynamical coupling time, and is thus of the order of 5 days for a neutron star with a 10-s rotation period.

Concluding remarks

We have described in this article the key role which synoptic observations and detailed analysis of the timing data of individual pulsars has played in bringing about a substantive change in perspective on post-glitch relaxation and the astrophysical evidence for neutron superfluidity. Without observational data of this quality there would have been little incentive to

develop a detailed theory of pinned vortex motion. Future careful observations of Crab, Vela and other pulsars will be of assistance in pointing out directions in which the theory can be improved and refined.

Much work has been done on neutron-star superfluidity which, unfortunately, there has not been space to discuss here. This includes work on the nature of pion condensates in neutron stars^{11,12,62,63}, neutron-star cooling⁵¹, the dynamics of moving vortex lines⁶⁴, as well as work in progress (M.A.A., R. Nandkumar and D.P., in preparation) on information concerning vortex creep theory which may be provided by the recent analysis (ref. 65 and P. Boynton and J. Deeter, in preparation) of timing noise observations to 23 pulsars in addition to Crab and Vela.

It could be argued that, although a convincing case has been made for crustal neutron superfluidity, there is little observational evidence for core neutron superfluidity, as the calculated rapid coupling of the core superfluid to the crust rules out post-glitch behaviour as a way to observe core superfluids. Better observations of pulsar surface temperatures and improved theories of neutron-star cooling may offer the best prospects for determining the role played by core superfluids. As we have noted, rapid cooling of pulsars during the epoch from $\sim 10^3$ to 10^4 yr is required by the internal temperatures inferred above for the Crab and Vela pulsars. This may provide a cogent theoretical and observational argument in favour of pion condensation, but more work will need to be done before any definitive conclusions can be reached.

We thank our colleagues in Urbana for many helpful discussions, Radha Nandkumar for a numerical computation and Fred Lamb and Noriaki Shibasaki for critical reading of the manuscript. This work has been supported in part by NSF grant PHY80-25605 and NASA grant NSG-7653.

Punctiform initiation of seafloor spreading in the Red Sea during transition from a continental to an oceanic rift

Enrico Bonatti

Lamont-Doherty Geological Observatory, Columbia University, Palisades, New York 10964, USA

Transition from a continental to an oceanic rift occurs in the Red Sea by initial emplacement of oceanic crust in regularly spaced 'hot points', which serve as nuclei for axial propagation into segments of oceanic crust accretion and for initiation of seafloor spreading. Hot points develop above upwelling mantle diapirs caused by density/viscosity inversion beneath continental and oceanic rifts.

AN important goal in earth science is to understand how the transition from a continental to an oceanic rift occurs in time and space, which will further our knowledge of oceanic Atlantic-type passive margins. This transition, which occurred along the proto-Atlantic rift 160–90 Myr ago, can be observed today in the northern Red Sea. Based on morphotectonic, magnetometric, seismic-reflection and petrological data from this region, I will attempt to demonstrate that: (1) injection of oceanic crust takes place initially in punctiform hot areas axially spaced ~50 km apart; (2) activation of hot points shows a northward time progression; and (3) each hot point serves as a nucleus for axial propagation of the zone of oceanic crust accretion into linear segments of spreading. I will also explain the punctiform initiation of seafloor spreading in terms of inferred patterns of upper mantle upwelling beneath the Red Sea, and suggest that the same model can be applied to the initial opening of the Atlantic rift.

Plate-tectonic reconstructions of the Red Sea/Gulf of Aden region^{1–5} suggest that, although emplacement of oceanic crust between Arabia and Africa initiated in the Gulf of Aden as early as ~10 Myr ago⁶, it started more recently in the Red Sea⁷. An axial rift valley with strong magnetic signature is present almost continuously in the southern Red Sea between 16° and 19° N. Vine–Matthews-type axial magnetic anomalies indicate initiation of seafloor spreading by injection of basalt crust in a narrow axial zone ~5 Myr BP in a region around 17° N, but more recently to the north and south of this region⁸, in a pattern which suggests axial rift propagation⁹. Moving northward, the axial rift valley and associated magnetic signature become discontinuous and then disappear completely in the northern Red Sea (Figs 1, 2).

This description assumes that, outside the axial zone with clear-cut high-amplitude Vine–Matthews magnetic anomalies, the Red Sea is floored by thinned, stretched continental crust criss-crossed by diffuse basaltic dyke injections, a view supported by recent geophysical data collected at sea^{7,10–12} and by observations at Zabargad (St John) Island, an uplifted block of Red Sea lithosphere¹³. However, the concept that the whole width of the Red Sea formed by two stages of seafloor spreading, the first of which started as early as ~40 Myr BP, has also been proposed^{14,15}.

The axial zone of the Red Sea can be divided from south to north into the following regions (Fig. 1), based on their different morphotectonic and magnetometric characteristics^{7,8,12,16–18}: (1) rift valley region (17° N–19°30' N), with a relatively straight and continuous axial rift valley and linear magnetic anomalies; (2) multi-deeps region (19°30' N–22° N), with a complex pattern of axial deeps and troughs; (3) transitional region (22° N–24° N), with a few regularly spaced axial trough segments; (4) northern region (north of 24° N), with no axial rift valleys but a few

Fig. 1 Outline of the Red Sea, with the axial zone enclosed by the 500-fathoms isobath. The approximate location of the axial rift valley and of isolated deeps and troughs is indicated. Also shown are locations of earthquake epicentres of magnitude >4 recorded from 1953 to 1983. The axial zone has been subdivided into geotectonic regions (see text)

isolated deeps. The model proposed here is based primarily on results obtained from the transitional region.

Red Sea transitional region

Field work in this region (Fig. 2) has shown the existence of segments of axial troughs and deeps with high-amplitude magnetic anomalies, separated by intertrough zones which lack an axial rift valley and high-amplitude magnetic anomalies, and have continuous, thick sediment cover across the axis^{11,16–18}.

The transitional region axial trough segments, named (from south to north) Thetis, Nereus, Bannock and Vema^{11,16}, become shorter, narrower and shallower moving from south to north (Fig. 2a, b). The Thetis and Nereus segments display morphotectonic features typical of rift valleys of oceanic slow-spreading axial zones such as the Mid-Atlantic Ridge (MAR). They have

Fig. 2 Outline of the Red Sea transitional region where the axial troughs and deeps (Thetis-Hadarba, Nereus, Bannock and Vema) are shown enclosed by the 1,500-m isobath (insert *a*). A series of seismic reflection profiles taken across the Red Sea axis (locations indicated in insert *b*) is shown on the left of the figure, together with magnetic anomalies along the same profiles. The vertical broken line indicates the approximate axis of the Red Sea. Insert *b* shows the width and length of the Thetis-Hadarba, Nereus, Bannock and Vema axial trough and deeps, defined by the 1,500-m isobath. Length is estimated from the distance along the Red Sea axis taken from the southern end of the Thetis-Hadarba trough.

steep walls formed by inward-facing normal faults¹⁸ and a neovolcanic zone floored by young basalts with mid-ocean ridge basalt (MORB) affinity¹¹. A trough segment to the south of Thetis, termed Hadarba Deep¹⁶, merges with Thetis although the axes of the two segments are offset laterally by ~5 km (Fig. 2*b*). High-amplitude magnetic anomalies are present at Thetis¹⁵, although its scant coverage does not allow an accurate estimate of the time of initiation of seafloor spreading. Its wider, longer and deeper trough suggests that Thetis is older and more evolved than Nereus. Magnetic anomalies over the Nereus trough suggest the presence of oceanic crust and initiation of seafloor spreading ~1 Myr ago in sections across the northern and southern parts of the trough, but >2 Myr ago in sections from the central part of the trough¹¹. Thus, the Nereus axial trough could be considered a mini-propagating oceanic rift segment where oceanic crust was emplaced initially in a central spot which then served as a nucleus for axial propagation.

The next axial deep segment to the north of Nereus, the Bannock Deep, lacks a steep axial rift valley but shows a gentle graben-like morphology with continuous sediment cover except along one section where a 500-m-high basement protrudes from the sediment (Fig. 2, profile 83-5). This feature is probably a volcanic seamount because fragments of dolerite were recovered from it¹¹. Profiles taken across the axis a few kilometres north and south of the seamount indicate continuous sediment cover and a prominent fault aligned axially with the volcanic seamount (Fig. 2). Narrow high-amplitude magnetic anomalies are associated with the seamount and the axial fault.

The Vema axial deep consists of a relatively gentle depression with continuous sediment cover and no high-amplitude magnetic anomalies, but there is relatively high heat flow¹¹. A consistent pattern of axial high-amplitude magnetic anomalies is absent in the Red Sea north of the Vema Deep, although deeps and anomalies have been found at several isolated sites^{16,18,19}.

Punctiform initiation of seafloor spreading

The observations from the Red Sea transitional region lead to the following interpretations, summarized in part in Fig. 3:

(1) The initial breakthrough of oceanic crust and the beginning of organized seafloor spreading occurs in essentially punctiform hot areas located in axially oriented segments of tensional fissures. The initial breakthrough of oceanic crust would occur through continental crust which has been thinned, stretched and diffusely injected by basaltic dykes^{7,10,11}, although it could occur in ancient, cold oceanic crust if the two-stage opening model^{14,15} is accepted. The igneous body cropping out from the axis of the Bannock graben and the axial fault detected just south and north of this igneous body are examples of recent hot point formation.

(2) Axial propagation from each hot point gives rise to linear spreading segments⁹. This hypothesis is supported by the detection of magnetic anomalies, as old as 2-3 Myr in sections from the centre of the Nereus trough segment, but younger close to the tips of the segment.

(3) A northward progression can be detected in the time of initial activation of the punctiform areas of ocean crust emplace-

Fig. 3 Schematic model of the initiation of seafloor spreading in the Red Sea transitional region. *a-c*, Different stages in time. Stars indicate sites of hot points where the initial emplacement of oceanic crust occurs. Striped areas, continental; stippled areas, oceanic; open areas, intermediate continental crust stretched, thinned and injected by basaltic dykes. Arrows, discontinuities in the morphotectonic and magnetic axial pattern, predicted by the model.

ments. Although in the southern Red Sea (between 17° N and 18° N), seafloor spreading initiated ~5 Myr BP, emplacement of oceanic crust probably started between 2 and 3 Myr BP at Nereus; it started <1 Myr BP at Bannock and has not yet started at Vema. The observation that the Thetis trough is deeper and wider than Nereus suggests that it is more evolved, and is therefore older than Nereus. Relatively high heat flow, as detected within the Vema Deep¹¹, may be a precursor to oceanic crust emplacement and may therefore mark future hot points in the northern Red Sea.

(4) The distance between the centre points of Thetis, Nereus, Bannock and Vema is ~50 km (Fig. 2*b*), suggesting a regular spacing of the areas of upper mantle upwelling and oceanic crust initial emplacement.

(5) Axial propagation from each hot point will eventually lead to joining of the different rift segments. Discontinuities are likely to develop in the axial morphotectonic and magnetic lineations where the tip of rift segments derived from different hot points join (Fig. 3). Moreover, the axial troughs and deeps are not all aligned; some show lateral offsets (Fig. 2). These initial offsets in the segments of oceanic crust emplacement may or may not lead to the formation of initial transform faults.

(6) The regular segmentation of the axis of spreading (Fig. 3) is interrupted where the Red Sea lithosphere is intersected by pre-existing shear zones²⁰, which would prevent normal axial rift propagation and act as 'locked zones' in the sense described by Courtillot⁹.

I now consider how the proposed model, derived from observations in the transitional region, fits available data from other regions of the Red Sea.

Rift Valley region. The evolution of seafloor spreading from a punctiform initiation can be inferred from observations obtained in the southern Red Sea between 17° N and 19°30' N (Fig. 1). The relatively continuous axial trough and the associated high-amplitude magnetic anomalies imply a steady though asymmetrical seafloor spreading regime for the past few million years, with spreading being about two-thirds faster to the west than to the east^{8,16}.

A detailed investigation of the axial zone at 18° N, including direct submersible observations^{21,22}, has revealed a morpho-

tectonic structure of the axial trough similar to that of the MAR in the FAMOUS area, a neovolcanic zone with basalts similar to MORB, and a spreading rate averaging 1.6 cm yr⁻¹ for the past 3-5 Myr. A deep-tow profile (Fig. 4) of the axial zone at 17°30' N (ref. 23) confirmed a morphotectonic structure similar to that found in the FAMOUS area, and demonstrated asymmetrical spreading (≈ 5 mm yr⁻¹ to the east, 10 mm yr⁻¹ to the west) starting at 4.8 Myr BP. In the context of the proposed model it is of interest that the Rift Valley morphotectonic structures and high-amplitude magnetic anomalies run along the axis in this region for straight segments 30-50-km long, which are stepped laterally by small, 3-10-km transform or non-transform relay zones (Fig. 4) where the magnetic anomalies are weak and irregular¹². One such discontinuity was surveyed in detail at 18° N (ref. 21). The proposed model explains these discontinuities as marking sites where different rift segments meet, each created by longitudinal propagation from an initial hot point (Fig. 3).

Multi-deeps region. This region, located between the more evolved southern Red Sea and the transitional region (Fig. 1), displays a complex geotectonic situation: the straight axial rift valley is replaced by a network of deeps distributed partly in an 'echelon' pattern^{16-18,24}. Some of these deeps are thermally active at present and contain hot brines (for example, Atlantis II, Discovery), some are instead inactive²⁴. This complex geotectonic structure may be determined in part by the presence of a major transverse fracture zone intersecting the Red Sea axis^{17,20,25}, an interpretation supported by the clustering of recent earthquake epicentres in this area (Fig. 1), and by the orientation of magnetic anomalies transversal to the Red Sea axis¹⁷. This is one of three major fracture zones intersecting the Red Sea, the other two being the Zabargad and the Brothers fracture zones, all striking parallel to the Dead Sea-Aqaba fault²⁰.

Northern region. The Red Sea north of the Vema Deep lacks a regular pattern of axial rift valley segments and associated high-amplitude magnetic anomalies^{7,11}, though a few isolated deeps are present, some located off the axis (Fig. 1). Some are associated with magnetic anomalies; that is, Charcot Deep at 25° N, where non-MORB basalts intrude the sediment¹⁹, and Al Wajab Deep at 25°20' N, where the anomalies are lineated partly in a direction transversal to the Red Sea axis^{15,19}. Some of these deeps may represent small pull-apart basins caused by tectonics related to the fracture zone, such as Al Wajab, at the northeastern end of the Zabargad Fracture Zone, where the Red Sea axial direction shifts by $\approx 40^\circ$ (Fig. 1).

Following Cochran⁷, I interpret the northern Red Sea region as floored by thinned and stretched continental crust injected by diffuse basaltic intrusions. Probable examples of such intrusions are basaltic/gabbroic rocks from the Brothers Islets²⁶ and the Charcot Deep¹⁹, showing transitional or alkaline affinity, in contrast to the MORB-like characteristics of basalts from the Nereus Trough¹¹ and from other axial sites further south in the Red Sea²⁷. Thus, punctiform axial injection of oceanic crust and organized seafloor spreading have probably not yet started in the northern region of the Red Sea.

Mantle upwelling beneath the Red Sea

The punctiform model of initiation of seafloor spreading in the Red Sea implies that beneath each initial hot point there is a zone of preferential upwelling of upper mantle material. It is generally agreed that a broad thermal anomaly affects the upper mantle in major rift zones of the Earth. One of the tenets of plate-tectonic theory is that the asthenosphere/lithosphere boundary rises close to the surface along the axis of oceanic rifts²⁸. A rise of the upper-mantle isotherms and of the asthenosphere/lithosphere boundary has been documented for major continental rifts, such as the East African²⁹, Rio Grande^{30,31}, Rhinegraben³² and Baikal^{33,34} rifts. A rise of upper-mantle isotherms and a thinning and stretching of the lithosphere, probably resulting in part from convective heat transfer to its base³⁵, obtains also beneath the Red Sea rift, a view consistent

Fig. 4 A portion of the axial zone of the rift valley region of the Red Sea, with simplified bathymetry, from Backer *et al.*¹⁶, and structural lineations obtained by a GLORIA sidescan survey, from Garfunkel *et al.*¹². Arrows indicate discontinuities in the axial morphotectonic lineations observed by Garfunkel *et al.*¹². Insert shows details of one such discontinuity at 18°, simplified from Zonenshajn *et al.*²¹. Isochrons (in Myr), based on magnetic anomalies, are indicated. Thick full line, present axis, dashed thick line, fossil axial segment; shadowed area, outer slopes of rift valley.

with a broad band of high heat flow³⁶ and positive gravity anomaly³⁷ extending across the entire width of the Red Sea.

Continuous upwelling and decompression of upper-mantle material below rift zones leads to partial melting. A low-density/viscosity layer containing a continuously replenished small melt fraction would result, sandwiched between material of higher density and viscosity. The low density of this layer is enhanced by the probability that the upwelling mantle is injected by metasomatic, H₂O- and CO₂-rich fluids, resulting in H₂O-containing phases, such as amphiboles. This mantle metasomatism is important below continental rifts³⁸.

The presence beneath the Red Sea of an upper mantle zone containing a melt fraction and affected by metasomatism is suggested by studies of a mantle-derived spinel lherzolite body uplifted on Zabargad Island (Fig. 2b), probably during the early stages of Red Sea rifting^{13,39}. The lherzolite body contains zones of plagioclase peridotite, probably representing small fractions of melt trapped by lherzolites in the upper mantle, as well as amphibole peridotites produced by reactions of metasomatic fluids with the lherzolite⁴⁰.

The density/viscosity inversion in the upper mantle can be treated as a Rayleigh-Taylor-type instability, an approach which has been used to model the distribution of volcanic activity along island arcs⁴¹ and oceanic spreading zones^{42,43}. Theory and experiments^{41,44-47} indicate that the interface between a high density/viscosity upper layer and a layer below with lower density/viscosity develops a sinusoidal instability that may evolve into a pattern of λ -spaced injections of the lower density fluid into the denser layer above. The density contrast affects the velocity of upwelling of the diapirs according to Stoke's law. Their spacing, λ , is related to the ratio of the thicknesses of the upper and lower layer, h_1/h_2 , and the ratios of their viscosities, μ_1/μ_2 (refs 45-47).

In the case of the Red Sea rift, the low-density upper mantle

zone can be assumed to be elongated in shape and of limited width. Provided $h_1 > h_2$, the spacing of the diapirs surging from the lower layer is approximated by^{41,45,46}:

$$\lambda = \frac{2\pi h_2}{2.15} (\mu_1/\mu_2)^{1/3}$$

Assuming μ_1 to be of the order of 10^{20} P^{48,49}, μ_2 can be estimated as being lower by 2-4 orders of magnitude, depending on the degree of partial melting chosen for h_2 and on the temperature and pressure contrast of the two layers. The thickness of h_2 depends on the upper mantle thermal regime of the particular rift being considered. Assuming h_2 as the layer containing melt within the 5-10% range, its thickness beneath the Red Sea axis should be a few kilometres, as estimated from data from Iceland⁵⁰ and mid-ocean ridges^{43,48}. If $\mu_1/\mu_2 = 10^3$ and $h_2 = 2$ km are chosen, a spacing slightly over 50 km is obtained for the upwelling diapirs.

Upwelling of the diapirs would result in an increased degree of melting, with the melt tending to segregate from its parent, collect towards the top of the diapirs and hence be injected into the crust. The attenuated thickness of the Red Sea crust would permit the 'asthenosphere geoid'^{51,52} and hence the melt to reach the sea floor. This mantle-driven pattern leading to the punctiform geometry of initial breakthrough of oceanic crust (Fig. 5), however, is interrupted where the Red Sea lithosphere is intersected and disrupted by pre-existing fracture zones, as in the multi-deeps region and in the Zabargad Fracture Zone.

The northward time progression in the activation of the hot points and in the evolution of seafloor spreading in the Red Sea suggests that the asthenospheric diapirs are superimposed on a broader zone of shallow hot upper mantle which may be moving as a wavefront towards the northern Red Sea (Fig. 5).

Axial propagation from each initial hot point could take place by mechanisms similar to the asthenospheric longitudinal flow

Fig. 5 Schematic and hypothetical cross-section along the axis of the Red Sea, showing regularly spaced asthenospheric diapirs in the transitional region, possibly caused by Rayleigh-Taylor instability in the upper mantle, superimposed on a broad wavefront of shallow hot mantle moving northward beneath the Red Sea.

Fig. 6 Spacing of axial volcanism in continental, proto-oceanic and oceanic rifts, versus spreading rate for the oceanic rifts. Data for the East Pacific Rise (EPR), MAR, Galapagos rift and Juan De Fuca Ridge are from Crane⁴³. Data for the Red Sea are from the present paper, for Iceland they include Quaternary and Recent volcanism of the East Volcanic Zone, from Sigurdsson and Sparks⁵⁶; for North Kenya, Ethiopian and Afar rifts they include Quaternary and Recent volcanism, from Mohr and Wood⁵⁷.

described by Courtillot⁹ and Vogt⁵³, and would result in axial spreading segments similar to those 30–50-km long observed in the rift valley region of the southern Red Sea. Interestingly, Mesozoic (155–108 Myr BP) magnetic anomalies from the western North Atlantic reveal that close to the time of opening, the early Atlantic accretionary axis was divided in segments

each ~50 km long with discontinuities of the magnetic anomalies, not necessarily associated with transform offsets, between each segment⁵⁴. Therefore, it seems that the punctiform model of initiation of seafloor spreading proposed for the Red Sea can also be applied to the early Atlantic rift.

Evolution from continental to oceanic rift

Structural studies of peridotites from ophiolite complexes suggest vertical flow of upper-mantle material beneath oceanic ridges, with upwelling zones spaced 50–100 km apart⁵⁵. Crane⁴³ noted that the spacing between areas of upwelling and igneous activity in oceanic zones of crustal accretion is related to spreading rate, that is, ~150 km along the fast East Pacific Rise, ~100 km along the intermediate Galapagos rift and Juan de Fuca Ridge, and ~50 km along the slow MAR. A regular spacing of ~40 km has been noted for active volcanoes in the eastern volcanic zone of Iceland, part of the MAR⁵⁶. The concept of regularly spaced volcanism can be extended to continental rifts: a spacing of ~40 km has been reported for Pleistocene and active volcanoes of the northern Kenya and Ethiopian rifts, and of 30–10 km for those of the Afar rift⁵⁷. The increase in spacing of hot points from continental to proto-oceanic, to slow, intermediate and fast oceanic rifts (Fig. 6) is paralleled by an inferred uplift of sub-rift isotherms and asthenosphere/lithosphere boundary, an increase in the degree of upper-mantle melting and a change in melt chemistry from alkaline to transitional to tholeiitic and to MORB. The first factor above, causing an increase in the thickness of the zone of partial melting from continental to slow to fast-spreading rifts^{43,48}, would determine a corresponding increase in the spacing of asthenospheric diapirs and volcanism. Thus, the transition from continental to oceanic rift as seen in the central Red Sea could be considered an important step in a continuum of rift processes, related ultimately to the evolution of mantle thermal waves.

The field work which led to this paper was sponsored by the Italian Research Council (CNR). I thank the officers and crew of RV *Bannock*; D. Breger, P. Colantoni, K. Crane and M. Taviani for collaboration; and J. Cochran for help in modelling the magnetic anomalies. The research was supported by NSF grant O.C.E. 83-15933 and by ONR contract N00014-8-C-0098. Contribution no. 3833 of the Lamont-Doherty Geological Observatory.

Correcting an immune-response deficiency by creating E_α gene transgenic mice

Marianne Le Meur, Pierre Gerlinger, Christophe Benoist & Diane Mathis

Laboratoire de Génétique Moléculaire des Eucaryotes du CNRS, Unité 184 de Biologie Moléculaire et de Génie Génétique de l'INSERM, Faculté de Médecine, 11 rue Humann, 67085 Strasbourg Cedex, France

We have introduced a cloned E_α^k gene into embryos of mice incapable of expressing their endogenous E_α genes. The transcription of E_α^k was accurate and tissue-specific in the resulting transgenic lines and, in macrophages, E_α^k transcription could be induced by γ -interferon. The injected gene conferred on the genetically deficient host strain the ability to mount an immune response to a synthetic polymer.

THE immune response to a foreign antigen involves the highly regulated expression of several specific gene sets. Mounting a successful antibody response to antigen challenge depends on mobilizing a repertoire of lymphoid cells: macrophages and dendritic cells that process and present antigen, B cells that effect the actual production of immunoglobulins and T cells that modulate the B-cell response.

A group of loci important in controlling the murine immune response have been mapped to the major histocompatibility complex (MHC) on chromosome 17 (see refs 1–5 for reviews). The 'immune-response' genes encode the Ia antigens, glycoproteins that occur at the cell surface as heterodimeric complexes, the A complex (A_α and A_β) and the E complex (E_α and E_β). Ia molecules are limited in distribution primarily to B cells and antigen-presenting cells (APC) including macrophages; certain immunological 'activators' such as γ -interferon (IFN- γ) and B-cell growth factor increase their expression. Immune-response genes are characterized by an extensive polymorphism, such that any two mouse strains have Ia chains that differ by 1–10% of their amino acids. Certain strains lack the E complex entirely.

The polymorphism of the Ia antigens seems to be the key to their function in the immune response. T cells can only 'see' foreign antigen in the context of an Ia complex and respond only when an APC 'presents' antigen in conjunction with an Ia molecule of the appropriate haplotype. Some antigens are presented in association with the E complex, others with the A, hence particular antigens are said to be E- or A-restricted. T cells activated in response to antigenic stimulation are essential for the B-cell response; this T-B interaction is also subject to 'restriction' by Ia molecules of the appropriate haplotype. The net result of joint antigen-Ia recognition by T cells is that when challenged with a given foreign antigen, antibody is produced depending on the particular Ia alleles expressed.

Recently, the genes for all four Ia chains have been cloned and multiple alleles of each sequenced². Experiments are being performed to localize the regions of each chain involved in restriction, and to define the mechanisms involved in the regulation of Ia gene expression throughout B-cell development and in response to inducers. As the immune response is a phenomenon involving interacting cells and multiple coordinately expressed gene products, we examined Ia expression and function in the whole organism by injecting Ia genes into mouse single-cell embryo pronuclei and identifying the resultant transgenic mice. Recent experiments injecting immunoglobulin, elastase and transferrin genes and some genes under the control of the metallothionein promoter have documented expression of these genes in a tissue-specific or at least a tissue-preferential fashion^{6–14}.

Here we demonstrate the use of transgenic mice in studying Ia expression and function. Mice of the $H-2^s$ or $H-2^b$ haplotypes do not express the E_α gene because of a deletion that removes its promoter region and first exon^{15,16}, consequently they cannot produce antibody in response to

E-restricted antigens such as the synthetic polymer poly(Glu⁵⁷Lys³⁸Phe⁵) (GLØ). We have injected the E_α^k gene into $H-2^{(b \times s)}$ hybrid mouse embryos. The resulting transgenic mice transcribe the E_α^k gene in a tissue-specific manner, express heightened levels of E_α in response to IFN- γ and assemble an E_α^k/E_β^s or E_α^k complex at the cell surface that can be recognized by monoclonal antibodies. Finally, as evidence of the overall efficacy of the injected E_α^k gene, the transgenic mice can produce antibody in response to GLØ.

E_α^k gene incorporation

The E_α^k gene from strain A/J mice has previously been cloned into λ Charon 4 (ref. 17). A partial restriction enzyme map of this clone is presented in Fig. 1a, which also shows the position of a 600-base pair (bp) deletion at the 5' end of the E_α gene from $H-2^b$ and $H-2^s$ mice. This deletion precludes E_α gene transcription in these strains because it includes the promoter region and the first exon¹⁶.

We injected the cloned E_α^k gene into the male pronucleus of F_2 hybrids derived from C57BL/6 $\times$ SJL hybrid crosses. (Note that SJL mice are $H-2^s$ and C57BL/6 are $H-2^b$.) This strain combination was chosen because it produces vigorous embryos⁷, is easy to manipulate and the progeny, $H-2^b$ and/or $H-2^s$, would not transcribe the endogenous E_α gene. In one experiment we injected the entire λ clone; 21 offspring developed from 88 surviving embryos, one of which (no. 23) had incorporated E_α^k . In a second experiment, we injected the purified 8.2-kilobase (kb) *Bgl*I fragment which contains all the E_α exons plus 2 kb of DNA 5' to the cap site and 1.4 kb 3' to the poly(A) addition site (see Fig. 1a). Of 273 surviving embryos, 16 were born live, including one (no. 16) that had incorporated E_α^k .

Figure 1b shows a Southern blot of tail DNA digested with *Bam*HI/*Eco*RV and hybridized with a small fragment (probe 1) entirely contained within the E_α deletion of $H-2^b$ and $H-2^s$ mice. Only the E_α^k gene should generate a signal with this probe (see Fig. 1a). Mice Ea16 and Ea23 exhibit a *Bam*HI/*Eco*RV fragment indistinguishable in size from that of A/J mice which contain two E_α^k genes per diploid genome. In contrast, Ea7 did not incorporate the injected DNA and thus provides a useful negative control.

The blot in Fig. 1c shows *Hind*III/*Eco*RV digests hybridized with probe 2, identified in Fig. 1a. Lane 1 of Fig. 1c shows the pattern expected from an E_α^k gene: a large band of ~6.6 kb containing all the E_α exons and a small band of ~1.8 kb containing sequences 5' to the coding region. The $E_\alpha^{b,s}$ patterns are seen in the next two lanes. The large band is smaller than for E_α^k because of the 600-bp deletion; the small band is larger than for E_α^k because of a polymorphic *Hind*III site (D.M. and C.B., unpublished observations). Mouse 23 exhibits all the bands characteristic of the E_α^k and $E_\alpha^{b,s}$ genes, whereas mouse 16 has the large bands diagnostic of E_α^k and $E_\alpha^{b,s}$ and the small band of only the latter. The small E_α^k band was not expected because the 5' border of the *Bgl*I fragment injected into mouse 16 is contained in the small *Hind*III/*Eco*RV fragment (see Fig. 1a).

Fig. 1 Integration of the E_α^k gene into the genome of transgenic mice. *a*, Map of the E_α^k gene in the λ clone $\lambda A/J$ p34.13 (ref. 17). Thick lines, exons; thin lines, introns and flanking sequences; dashed boxes, vector arms. The deletion of the $H-2^b$ and $H-2^s$ haplotypes in E_α is shown as a double-headed arrow. Brackets indicate the two probes used. Probe 1, a 320-bp *Acc*I/*Sac*I fragment (from position -220 to +100 with respect to the major site of initiation of transcription) that does not hybridize to DNA from $H-2^b$ and $H-2^s$ haplotype mice. Probe 2, a 2-kb *Sal*I fragment spanning ~1 kb on either side of the b/s deletion. Only the relevant restriction enzyme sites are shown. *Bam*, *Bam*HI; *Bgl*, *Bgl*I; *Hind*, *Hind*III; *R*V, *Eco*RV. *b*, *c*, Southern blot analyses (described in ref. 17) of tail DNA from several mice: A/J, C57BL/6 $\times$ SJL F₁ (B $\times$ S), and mice derived from injected eggs (E α 7, 16 and 23). In *b*, DNA was digested with *Bam*HI and *Eco*RV, and the blot hybridized to probe 1. *c*, The pattern generated with *Hind*III and *Eco*RV was revealed by probe 2. The band of high relative molecular mass in E α 16 results from incomplete digestion.

It is replaced by a slightly smaller band, whose size is consistent with the notion that many of the copies of E_α^k in mouse 16 are organized as tandem repeats. This blot demonstrates first, that the injected genes are not grossly rearranged in either mouse 23 or mouse 16, as shown by the intact 6.6-kb band containing all the exons. Second, by comparing within the same slot, the band intensities of fragments derived from the injected E_α^k genes with those from the endogenous $E_\alpha^{b,s}$ genes, we can accurately quantitate E_α^k copy number. Thus, mice 23 and 16 contain, respectively, ~4 and 12 copies of the intact E_α^k gene per diploid genome in tail tissue. Similar results were obtained with liver DNA.

To ascertain whether these genes were incorporated in the germ line, we mated mice 23 and 16 with mice from strain C57BL/6 ($H-2^b$). Mouse 23 produced nine young, four of which had integrated the E_α^k gene, whereas 7 of the 16 offspring from mouse 16 had the E_α^k gene. These values suggest that, for each transgenic mouse, all copies of the injected gene had integrated into the same chromosome. Southern blots of *Bam*HI digests confirmed that the offspring from mouse 16 had inherited the same number of copies, and that this number was the same as for their parent (data not shown).

E_α^k expression

The E complex is absent from most murine cells, but is present in high concentrations on B cells and activated macrophages⁴. Thus, we chose spleen tissue for the initial analysis of transcription from the injected E_α^k gene. A Northern blot of total spleen RNA hybridized with an E_α complementary DNA probe (Fig. 2*a*) shows that transgenic mice E α 16 and E α 23 express the same 1.25-kb E_α transcripts as control mice of haplotype $H-2^{b \times a}$. It should be recalled that neither the E_α^b nor E_α^s genes are transcribed, so that all the visualized RNA derives from the E_α^k gene.

To confirm the accuracy of transcription, we mapped initiation sites on the E_α^k gene in the spleen. RNA was hybridized with a single-stranded DNA probe labelled at the 5' end. If initiation were correct, treatment of the DNA-RNA hybrids with S₁ nuclease should result in a pair of protected fragments ~100 bp

Fig. 2 Accurate expression of the integrated E_α^k gene. Total RNA was prepared from spleens of different control or transgenic mice and analysed by Northern blotting (*a*) or S₁ nuclease mapping (*b*). The nomenclature for the mouse strains is described in Fig. 1 legend, except for B $\times$ A which is a C57BL/6 $\times$ A/J F₁ hybrid. The filter in *a* was probed with an E_α cDNA clone¹⁷. In *b*, the probe was a 320-nucleotide (nt) single-stranded DNA fragment (*Acc*I/*Sac*I; see Fig. 1 legend). Hybridization with E_α mRNA protects a set of fragments ~100 nucleotides long, which was revealed by electrophoresis on a urea-acrylamide gel followed by autoradiography. M, relative molecular mass markers with sizes of 147, 122, 110, 90 and 76 nucleotides. Techniques and conditions have been described elsewhere¹⁷.

long, as is seen in Fig. 2*b* for a B $\times$ A mouse. The complexity of the pattern results from multiple initiation sites (see discussion in ref. 17). In spleen RNA from mice 16 and 23, initiation on the E_α^k gene was accurate. Mouse 23 seems to produce fewer transcripts than the B $\times$ A hybrid, whereas mouse 16 makes more. These differences are more apparent than in the Northern blot, probably because the S₁ assay is less sensitive to partial RNA degradation.

The specificity of transcription was evaluated by S₁ analysis of RNA from several other tissues (Fig. 3). In the B $\times$ A control, high levels of E_α messenger RNA were observed in spleen and lung tissue, lower levels were detected in the kidney and almost no E_α mRNA could be measured in the liver, heart and brain. The results with lung and kidney are somewhat surprising in view of the contention that Ia genes are expressed mainly on B cells and macrophages. However, Northern blots of lung and kidney RNA hybridized with an immunoglobulin κ -chain probe indicated that these tissues are contaminated by lymph nodes, macrophages and/or significant blood infiltration (data not shown; ref. 14). Transgenic mice E α 16 and E α 23 exhibit the same pattern of tissue distribution: high levels in spleen and lung and low or undetectable levels in kidney, liver, heart and brain (Fig. 3). This S₁ assay may not detect aberrant transcripts initiating in regions of the E_α gene not covered by the rather short probe. To exclude this possibility, we also ran Northern blots on RNA from the different tissues and did not detect anomalous bands, confirming the S₁ mapping results (data not shown).

Another method of assessing tissue-specific expression of the injected gene is to compare the amount of A_α and E_α^k transcripts in various tissues. A_α has a high level of sequence homology with, an identical tissue distribution to, and a functional role analogous to the E_α chain. In S₁ experiments similar to that illustrated in Fig. 3, RNA was hybridized simultaneously with E_α and A_α probes (see Fig. 3 legend). Clearly, the bands attributed to E_α mRNA (100 bp) have the same pattern of distribution as those resulting from A_α transcripts (128 and 260 bp). We concluded that the injected E_α^k gene is transcribed coincidentally with the endogenous A_α gene in the six tissues studied. In other experiments, we have confirmed this tissue-specificity of expression in one offspring from each of mice 16 and 23.

Evidence for the tissue-specificity of transcription is

Fig. 3 Tissue-specific expression of E_{α}^k in transgenic mice. E_{α} and A_{α} mRNA was analysed in various tissues from three mice by S_1 nuclease mapping of total RNA. For E_{α} , the probe was the same as in Fig. 2. For A_{α} , the probe was an 800-bp *Hind*III fragment from an A_{α}^b cDNA clone, which was labelled at the *Hind*III site at position 262 and extended through the first domain, the leader and the plasmid sequences. A_{α}^b mRNA protects a 262-nucleotide fragment. The second A_{α} band on the gel results from an internal S_1 nuclease cut when the probe is hybridized to A_{α}^b mRNA; allelically polymorphic residues of the s haplotype²¹ locally destabilize the hybrid enough for partial S_1 nuclease cleavage under our conditions. The tissues investigated were spleen (Sp), liver (Li), lung (Lu), heart (He), kidney (Ki) and brain (Br), from a C57BL/6 $\times$ A/J F_1 hybrid (B $\times$ A), and from E α 16 and E α 23.

thus twofold: first, E_{α}^k expression in transgenic mice closely parallels that in the B $\times$ A control; second, transcription of the E_{α}^k and the endogenous A_{α} genes follows a very similar pattern. However, because some of the tissues exhibit a high background resulting from blood infiltration, macrophages or lymph nodes, we cannot eliminate the possibility that the transgenic mice exhibit low levels of aberrant transcription in these tissues. This might be the case in mouse 16 liver, where a low level of E_{α} mRNA (a few per cent of that seen in the spleen) is observed.

As a measure of cell-type specificity of expression, we compared the distribution of the A and E complexes on spleen cells by labelling them with fluorescent anti-E and anti-A monoclonal antibodies and visualizing them by two-colour cytofluorometric analysis. Expression of the A complex on the cell surface depends on transcription of the endogenous A_{β} and A_{α} genes; expression of E requires transcription of the endogenous E_{β} and the injected E_{α} genes. Thus, we could not ask whether E_{α}^k was transcribed in cells in which the other Ia chains did not occur because we would not detect it on the cell surface (resulting from the absence of E_{β}). However, we could determine whether cells expressing the A complex (and thus also transcribing the endogenous E_{β}) all exhibit an E complex on the cell surface. Figure 4 shows that the spleen cells of one of the progeny of mouse 16 consist almost entirely of two populations: $A^{-}E^{-}$ and $A^{+}E^{+}$. As expected, there is no $E^{+}A^{-}$ component. The fact that there is no significant $A^{+}E^{-}$ population indicates that essentially all cells that synthesize the endogenous A_{α} , A_{β} and E_{β} chains also transcribe E_{α}^k . A few cells trail into the $A^{+}E^{\text{dull}}$ area, but this minor component can also be seen in spleens from B $\times$ A controls.

E_{α}^k gene induction

Expression of all four Ia antigens is stimulated greatly in macrophages by treatment with supernatants from activated T cells or with purified IFN- γ . This induction was first described for cell-surface Ia molecules (see ref. 18 for review), but more recently has been documented for stable mRNA transcripts^{17,19}. To determine whether the injected E_{α}^k gene was similarly sensitive to IFN- γ induction, we prepared peritoneal macrophages from E α 16 and E α 23 third-generation mice, cultured them in the presence or absence of recombinant IFN- γ for 60 h and quantitated A_{α} and E_{α} mRNA levels by S_1 mapping.

Figure 5 clearly shows an induction of A_{α} and E_{α}^k mRNA in the IFN- γ -treated macrophages from both transgenic mice. The levels of Ia induction are similar to those that we have observed for E_{α}^k in repeated experiments on other mice.

Fig. 4 I-A-positive spleen cells are also I-E-positive in the E α 16 transgenic line. Twenty hours after concanavalin A activation, spleen cells were stained with fluorochrome-labelled monoclonal antibodies specific for the A or the E complex. For each cell, red and green fluorescence was detected by flow cytofluorometry. On this two-parameter representation, single cells appear as thin dots; thicker dots indicate several cells in the same channel.

Methods. Antibodies were purified from ascites fluid by affinity chromatography on protein A-Sepharose (Pharmacia). The anti-I-A antibody BP107 (ref. 22) was directly conjugated to fluorescein isothiocyanate (FITC) as described elsewhere²³. Antibody 14.4.4, specific for the E complex, was conjugated to phycoerythrin (PE; Molecular Probes, Ore) according to Oi *et al.*²⁴. After purification on Lympholyte M (Cedarlane), lymphocytes were stained in one step in FWS (phosphate-buffered saline supplemented with 3% calf serum, 30 mM HEPES and 0.1% sodium azide). Incubation was for 30 min on ice with saturating amounts of antibody. After two washes in FWS, the cells were examined on an ATC 3000 flow cytometer (ODAM, Wissembourg) equipped with an Innova-90 argon laser set on the 488-nm line for excitation of both fluorochromes. Signals from lymphocytes were selected by electronic gating according to size (impedance measurement) and laser scatter. Emission from the fluorochromes was separated by a 555-nm SWP017 dichroic mirror (Melles Griot, Irvine) and further elimination of signal cross-contamination was accomplished with a 550-nm SWP015 short-pass filter in front of the FITC detector and a 575-nm 5151 long-pass filter (Oriol, Stratford) in front of the PE detector. A small degree of electronic compensation was also applied before logarithmic amplification. Average channel numbers on the red and green scales were: $A^{-}E^{-}$, 73 and 52; $A^{+}E^{+}$, 160 and 210; unstained cells (or cells stained with irrelevant antibodies) were centred around channels 71 and 45 in the red and green scales, respectively.

Fig. 5 Injected E_{α}^k gene response to IFN- γ . Peritoneal macrophages were elicited with thioglycolate (3 days)²⁵ and subsequently cultured for 60 h in the presence (+) or absence (-) of 100 U ml⁻¹ recombinant IFN- γ . RNA was prepared and analysed by S₁ nuclease mapping as described in Fig. 3 legend. The mice were from the F₂ of a backcross to C57BL/6.

Functional E_{α}^k gene product

The ability of an animal to make antibody in response to the synthetic antigen GL $\emptyset$ is dependent on expression of the E complex. The mice that served as hosts for the injected E_{α}^k gene do not respond to GL $\emptyset$ because they are the progeny of (H-2^b $\times$ H-2^s) hybrid crosses and thus do not express any E_{α} . However, if the injected E_{α}^k gene makes a functional product, the animal should be able to mount a response to GL $\emptyset$. To test this possibility, we injected some of the offspring of mice 16 and 23 with GL $\emptyset$ according to the protocol described in Fig. 6 and evaluated their secondary response by quantitating serum levels of anti-GL $\emptyset$ antibody. Note that these offspring derive from a C57BL/6 $\times$ transgenic mating, so only about half carry the injected E_{α}^k gene. Ovalbumin was injected at the same time to serve as a positive control; as it is an A-restricted antigen, b- and s-haplotype mice can respond.

Figure 6 shows a perfect correlation between the presence of the E_{α}^k gene and the ability to make antibody in response to GL $\emptyset$. The titres and mRNA levels for the offspring of mouse 16 are generally higher than those of mouse 23 (Figs 2b, 3). There is some variability in the response for different mice from the same transgenic parent, but we have also seen variable antibody titres for the B $\times$ A controls, and thus we do not lend much significance to the range of responses. The lower values cannot be attributed to the H-2 haplotypes (see Fig. 6, beneath the histogram), to a difference in the number of E_{α}^k genes that have been inherited (data not shown) or to general immunodeficiency (because of a healthy ovalbumin response).

Conclusion

We have injected a cloned E_{α}^k gene into embryos of mice incapable of expressing their endogenous E_{α} genes. The cloned DNA was incorporated into the germ line and inherited in a normal mendelian fashion. Expression of the E_{α}^k gene is tissue-specific, similar to transcription of the endogenous homologue, A_{α} . In peritoneal macrophages, E_{α} mRNA synthesis is responsive to induction by IFN- γ . The injected gene is transcribed accurately and specifically in several cell types, and the animals can mount a normal immune response.

Our results show that tissue-specific expression and inducibility by IFN- γ of the E_{α} gene is conferred by sequences within or relatively close to the structural gene: mouse 16 was injected with an 8.2-kb fragment containing only 2 kb upstream from the cap site and 1.4 kb downstream to the poly(A) addition site.

Fig. 6 E_{α}^k -positive transgenic mice mount an effective immune response to the synthetic antigen GL $\emptyset$. Fifteen mice, derived from crossing E α 16 or E α 23 with C57BL/6, were challenged with the terpolymer (Glu-Lys-Phe), and specific antibody titres were measured in a sandwich enzyme-linked immunosorbent assay. Bars represent the values (in arbitrary units) obtained for the different offspring and for control B6 $\times$ A/J or B6 $\times$ SJL F₁ hybrids. MHC haplotypes are shown below the E_{α}^k -status, and were determined for the transgenics by Southern blotting of genomic DNA cut by PstI and probed with an A_{α} cDNA fragment. PstI generates polymorphic A_{α} bands which enable the H-2^b and H-2^s haplotypes to be distinguished. NMS, normal mouse serum.

Methods. Mice were taken at 2 months old and were injected intraperitoneally at days 1 (in complete Freund's adjuvant) and 21 (in saline), each time with 25 μ g GL $\emptyset$ and 25 μ g chicken ovalbumin (OVA). Sera were collected at day 28 and tested for specific antibodies by incubating dilutions in microtitre plates previously coated with GL $\emptyset$ or OVA. After washing off unbound antibodies, we added to the wells an alkaline phosphate-conjugated goat anti-mouse immunoglobulin antibody (Cappel); this was followed after 2 h by extensive washing. Bound enzyme was measured by the rate of conversion of p-nitrophenyl phosphate, with several absorbance readings taken on a Titertech Multiscan. Titres were calculated from the linear portions of the curves obtained, and are expressed in arbitrary units by comparison with a laboratory standard serum.

Therefore, in future experiments it will not be necessary to inject large cosmid clones that may contain adjacent genes.

By the injection of a single gene we have endowed a genetically deficient host strain with a new immune response. A successful antibody response implies the involvement of the E complex in various cell/cell interactions, for example, APC-T cell, T-B cell. In addition, T cells must be 'educated' to the E complex in the thymus. That the E_{α}^k gene product seems to function correctly in all the necessary immunological contexts allows the study of Ia function in the organism. The importance that mutant and recombinant mice have already had in studies elucidating the intricacies of the immune response cannot be underestimated. The generation of such strains is, however, limited to fortuitous mutations or crossovers, and unknown genetic segments can be carried along during the construction of lines (see, for example, ref. 20). It should now be much easier to create mouse strains which differ by only a single gene.

We thank R. Brinster, K. Illmensee, R. Jaenisch, D. Martin and V. Williams II for advice, Y. Quesneau for the cytofluorometric analysis, C. Irrmann for reimplanting the zygotes, and P. Gerber and P. Hickel for technical assistance. We also thank H. McDevitt, J. Monaco, G. Adolph, D. Landais, M. Ayane, G. Garcin and S. Candeias for gifts of materials and A. Staubli for tissue sections. Recombinant IFN- γ (produced by Genentech Inc.) was supplied by Boehringer Ingelheim. E.

Taubert, S. Phayboune, C. Marfing, and F. Mackay-Landau were responsible for building and maintaining the animal care facility. J. Kaibach, B. Boulay and C. Werlé assisted in the preparation of the manuscript. Finally, we thank P. Chambon for his continued support and interest and for having the

LETTERS TO NATURE

On the nature of the companion to Van Biesbroeck 8

L. A. Nelson, S. A. Rappaport & P. C. Joss

Center for Theoretical Physics and Department of Physics,
Massachusetts Institute of Technology, Cambridge,
Massachusetts 02139, USA

We present here the results of the first numerical evolutionary calculations for very low-mass stars (masses in the range of $0.01-0.1 M_{\odot}$) with ages up to the age of the Galaxy. Our calculations shed new light on the nature of the recently discovered object VB 8B (ref. 1), the companion to Van Biesbroeck's star no. 8 (VB 8; ref. 2), and support the identification¹ of this object as a low-mass star in which hydrogen burning was never able to establish thermal equilibrium. For plausible ages of this binary stellar system ($\geq 10^9$ yr), we estimate the mass, M , of VB 8B to be in the range $0.04-0.08 M_{\odot}$ (see also ref. 1 and refs therein). The object is supported primarily by degenerate electron pressure, and we find that its present values of central density and temperature are $\rho_c \approx 500-2,000 \text{ g cm}^{-3}$ and $T_c \approx 1.0-1.5 \times 10^6 \text{ K}$, respectively. The star VB 8 itself³⁻⁵ may also be a low-mass star which marginally failed to establish main-sequence hydrogen burning. Thus, the mass ratio for this binary system is probably not greatly different from unity, and we predict an orbital period of ≥ 40 yr. Our evolutionary tracks are also applicable to the interpretation of observations of other very low-luminosity dwarfs (see refs 3, 5-7). The study of such objects may be directly relevant to the development of an understanding of the 'dark matter' that has been inferred, from dynamical considerations, to be present in our Galaxy and many extragalactic systems (see, for example, refs 8, 9).

Several stars have been found to have either a mass close to or below that of the end of the hydrogen-burning main sequence (for example, Luyten 726-8A and B; Ross 614B; refs 6, 7, 10-12), or an effective temperature below that expected for even the lowest mass main-sequence star (for example, LP 271-25 = LHS 2924; ref. 5). Some of these stars are in binary systems whereas others have no detected companion. Such stars may be of sufficiently low mass ($\leq 0.08 M_{\odot}$ for a hydrogen-rich star^{13,14}) that they never achieve thermal equilibrium through hydrogen burning, and are candidates for 'brown dwarfs'. This is something of a misnomer, in that some stars with masses below the minimum main-sequence mass can attain effective temperatures quite comparable with those of ordinary late M dwarfs for a substantial interval of time ($\geq 3 \times 10^8$ yr) during their contraction phase. The existence of very low-mass ($\leq 0.01 M_{\odot}$), unseen companions to nearby stars has also been inferred by astrometric

techniques^{15,16}, but the reliability of these detections remains uncertain (see ref. 17).

In addition, the presence of low-mass ($M \leq 0.1 M_{\odot}$) stars has been inferred in several interacting binary systems, including two binary X-ray sources and several cataclysmic variables with orbital periods near the minimum in their orbital period distribution (see refs 14, 18, 19 and refs therein). In all cases, however, these binary systems are studied in X-radiation and/or visible light produced by the accretion of matter from the hypothesized low-mass secondary to a collapsed star (degenerate dwarf or neutron star). The low-mass star itself is not directly detected. Furthermore, in these systems, the secondary stars are thought to have attained their present low-mass state by transferring a large amount of their original mass to the collapsed star (or by loss of mass from the binary altogether). Thus, most of these low-mass interacting stars are probably not primordial: that is, they have evolved from more massive objects.

To get a better understanding of the object VB 8B, which is reported to have a radius, R , of $\sim 0.09 R_{\odot}$ and an effective temperature, T_e , of $\sim 1,360 \text{ K}$ (ref. 1), we have carried out evolutionary calculations for stars of mass $\leq 0.1 M_{\odot}$. We utilized a simplified stellar evolution code developed by Rappaport *et al.*¹⁹ and modified by Rappaport and Joss¹⁴ to carry out the present calculations. The basic simplifying features of the code are in (1) the treatment of the stellar structure, which is taken to be completely convective and is represented by an $n = 3/2$ polytrope, and (2) the matching of entropy in the stellar interior directly to that at the photosphere. The former approximation has been shown to be adequate^{6,13,18-20} for a low-mass star during its cooling from very early evolutionary stages all the way to a totally degenerate configuration. The assumption of matched entropies has been utilized successfully in the past¹⁴, and we have carried out further checks in the present work (see below). The code we utilize, however, cannot handle cold objects of mass $\leq 0.005 M_{\odot}$. For the present study, we have slightly modified the code to include the burning^{7,21} of a small quantity (5×10^{-5} by mass; see ref. 22) of primordial deuterium, and an approximate expression which incorporates the Coulomb corrections to the equation of state^{23,24}. This latter expression was adjusted so that the stellar radii we obtain for totally degenerate configurations almost exactly match the results of more detailed structure calculations by Zapolsky and Salpeter²⁵. Unlike some previous calculations of cooling curves for very low-mass stars (see 6, 7, 26 and refs therein), our evolutionary runs are continued to very low effective temperatures and the behaviour of the parameters is presented explicitly as functions of time. Stevenson²⁷ has carried out semi-analytical calculations of the cooling of degenerate dwarfs to very low temperatures, but, unlike the present study, his calculations did not follow the evolution of the stellar radius.

We considered stellar masses in the range of $0.01\text{--}0.10 M_{\odot}$, in increments of $0.01 M_{\odot}$. We note, that $0.01 M_{\odot}$ is an especially plausible operational definition of the dividing line between 'stars' and 'planets', because this is about the minimum mass for which the pressure support in the final equilibrium configuration is contributed principally by either thermal gas pressure or degenerate electron pressure, as opposed to atomic and molecular forces. Moreover, $0.01 M_{\odot}$ is about the minimum mass for which quasi-equilibrium thermonuclear fusion (in the form of deuterium burning) can ever be established (see below).

We tested two chemical compositions, one appropriate to Population I stars $[(X, Y, Z) = (0.70, 0.28, 0.02)]$ and the other appropriate to Population II $[(X, Y, Z) = (0.719, 0.28, 0.001)]$. We used three sets of radiative opacities; one^{19,28} simulated the effects of grain formation in the stellar atmosphere at low temperatures ($T_e \leq 2,200$ K; hereafter, opacity AG), while the other two, which ignored such effects, were adapted from the opacity tables derived by Alexander^{19,28} and the fitting formulae, due to Webbink (ref. 14 and personal communication), based on the Cox-Stewart²⁹ and Cox-Tabor³⁰ opacities (hereafter, opacities A and W, respectively). The effect of possible grain formation on the radiative opacities at low temperatures was approximated by setting the numerical value of the Alexander^{19,28} opacity coefficient equal to a constant for $T_e \leq 2,200$ K (see also ref. 18).

All initial stellar models had $R \geq 1 R_{\odot}$, which is at least 10 times greater than the radius of any plausible model of VB 8B, and were assumed to have negligible rotational angular momentum. If, however, the angular momentum were not significantly dissipated by the time the contracting protostar had reached a radius of $\sim 1 R_{\odot}$, then the early portions of the evolutionary cooling tracks could be quite different from those we present. On the other hand, it is quite plausible that some form of braking torque, possibly associated with a magnetic stellar wind (see ref. 31), will effectively despin the star, so that for stellar ages $\geq 10^7$ yr our evolutionary calculations should be valid. (For a recent review of some of the processes involved in star formation, see ref. 32 and refs therein.)

Figure 1 shows cooling curves for stellar models of several different masses; Fig. 1a and b show the evolution of the effective temperature and stellar radius, respectively. All models in Fig. 1 were generated with a Population I chemical composition and the AG radiative opacities. Note that the contraction of each stellar model is temporarily halted for times between $\sim 10^6$ and $\sim 10^7$ yr due to deuterium burning (see also ref. 7). After deuterium exhaustion, contraction resumes towards the final equilibrium state. For $M \geq 0.086 M_{\odot}$, the star achieves a state of thermal equilibrium (that is, arrives on the hydrogen-burning main sequence) within $\sim 10^9$ yr and has an effective temperature far greater than that measured for VB 8B [$1,360 \pm 200$ K (ref. 1)]. For lower mass stars, thermal equilibrium is never reached (except temporarily on the deuterium-burning main sequence) and the stars cool indefinitely. However, for a star whose mass is only slightly lower than the minimum mass for the hydrogen-burning main sequence, cooling times required to achieve $T_e \leq 2,000$ K may exceed the age of the Universe. We note that for $T_e \leq 2,000$ K the atmospheric radiative opacities become highly uncertain; however, we have found that the cooling timescales are rather insensitive to changes in the assumed opacity law.

We have repeated the evolutionary calculations presented in Fig. 1 for the other radiative opacities discussed above and for stars with a Population II chemical composition. The results are in qualitative agreement with those shown in Fig. 1. The implementation of opacity A has the effect of initially decreasing the cooling rate and then increasing the rate at later times. We found that the greatest overall change in the cooling timescale, relative to that obtained with the AG opacities, was about a factor of 3 and occurred for the $M = 0.01 M_{\odot}$ model. More typically, for other masses, the cooling times changed by a factor of < 2 . When opacity W is used, the change in the behaviour of the cooling rate is similar to that found for opacity A, and the effective temperatures are systematically raised by $\sim 10\text{--}15\%$ during the initial contraction phase. As a further test of the

Fig. 1 Evolutionary tracks for very low-mass stars with masses in the range of $0.01\text{--}0.10 M_{\odot}$. The effective temperature, T_e , and stellar radius, R , are shown as functions of elapsed time, t , in *a* and *b*, respectively. Each track is labelled with the corresponding stellar mass, in units of $M_{\odot}$. The plateau regions evident in the plots of radius versus time (near $t = 10^6\text{--}10^7$ yr) are due to the burning of a small quantity (5×10^{-5} by mass) of primordial deuterium. Stars with masses in excess of $\sim 0.086 M_{\odot}$ ultimately achieve thermal equilibrium through hydrogen burning (that is, they attain hydrogen-burning main-sequence status). Stars of lower mass cool indefinitely towards a completely degenerate configuration. For $T_e \leq 1,000$ K the displayed cooling curves become increasingly uncertain. Our values of T_e for $t \geq 3 \times 10^9$ yr are in good agreement with those calculated by Stevenson²⁷.

sensitivity of our results to the values of the radiative opacities at low temperatures, we have calculated several series of cooling curves where we adopted various (constant) values for the opacity coefficient at $T_e < 2,200$ K. We find that for changes in this constant opacity of up to two orders of magnitude, the cooling times change by only a factor of ≤ 2 . We caution, however, that extremely large changes in the opacity law might alter the stellar structure and surface-boundary conditions sufficiently to invalidate the simplifying assumptions that we have utilized in our code. Finally, in a similar series of tests, we have verified the insensitivity of our results to the assumption that the entropy in the stellar interior is equal to that at the photosphere.

We note that additional complications in the physics of the stellar interior, such as crystallization into a Coulomb lattice (see ref. 33) within some layers of the star, may occur at the lowest effective temperatures we consider. We have checked, in a self-consistent manner, that such effects should not affect our basic results obtained with the AG opacities for ages of $\leq 10^{10}$ yr. The effects of crystallization become important earlier during the evolution when the A or W opacities are used than when the AG opacities are employed.

If we assume that VB 8B is not exceptionally young (that its age is $\geq 10^9$ yr; ref. 1), then we can conclude from Fig. 1 that its mass must exceed $\sim 0.04 M_{\odot}$ in order for it not to have cooled below its current effective temperature. (However, observational

selection might favour the discovery of such objects when they are young and thus relatively bright; if this is the case, somewhat smaller values for the age of VB 8B might be allowed.) The effective temperature of a star with a mass $\geq 0.086 M_{\odot}$ is always much higher than that observed for VB 8B. For stars with masses in the range of ~ 0.04 to $\sim 0.08 M_{\odot}$, the radii and effective temperatures will be consistent with those observed for VB 8B during a substantial interval of time. Table 1 lists some of the physical properties of our stellar models in this mass range that have radii and effective temperatures similar to those of VB 8B.

It seems quite reasonable that VB 8 itself is also an extremely low-mass star which has a mass very close to that of a star at the end of the hydrogen-burning main sequence. According to Probst and Liebert⁵, its effective temperature is $\sim 2,400$ K. [We note, however, that temperature determinations in this range are highly uncertain, and the effective temperature of VB 8 could be somewhat higher (see ref. 1).] Table 1 also lists the properties of our stellar models with temperatures close to that observed for VB 8. A star with a mass of $\sim 0.08 M_{\odot}$ and an age of $\sim 2 \times 10^9$ yr would have properties consistent with those observed for VB 8 (refs 2–5). The absolute bolometric magnitude of such a star is 14.2. This value, together with the observed visual magnitude of ~ 16.9 (refs 2, 3) and the measured distance of 6.5 pc (ref. 2), implies a bolometric correction of -3.7 , a highly plausible value for a star with T_e in the range of $\sim 2,400$ – $2,700$ K (see refs 6, 11, 34). If we adopt masses of $\sim 0.06 M_{\odot}$ and $\sim 0.08 M_{\odot}$ for VB 8B and VB 8, respectively, and take the orbital separation to be $\geq 9 \times 10^{13}$ cm (ref. 1), we find that the orbital period of the system is ≥ 40 yr. Thus, the properties of this system are entirely consistent with those of a non-interacting binary consisting of a pair of stars whose current masses have not varied from their initial values.

Very low-mass stars have been suggested³⁵ to be a major component of the 'dark matter' that has been inferred, from dynamical considerations^{36,37}, to comprise about half the mass density in the vicinity of the Sun. Estimates of the space density of such stars, based on extrapolation from the observed numbers of low-mass stars that are on the hydrogen-burning main sequence (see, for example, ref. 38), can plausibly account for this 'missing mass'. Detailed studies of the detectability of such objects with ground-based instruments or future space observatories (such as the Hubble Space Telescope and the Space Infrared Telescope Facility) have been carried out by, for example, Staller and de Jong³⁸. The present work has yielded

more reliable cooling curves for very low-mass stars, so that this type of study should be repeated; we are carrying out such investigations and shall report our results elsewhere.

We thank D. McCarthy for a helpful introduction to this subject before publication of his results, and H. Graboske, J. McClintock, R. Probst, D. Stevenson and S. Tremaine for stimulating discussions. A radio jet associated with the supernova remnant G332.4+0.1 (Kes 32)

R. S. Roger, D. K. Milne, M. J. Kesteven, R. F. Haynes & K. J. Wellington

Division of Radiophysics, CSIRO, PO Box 76, Epping, New South Wales 2121, Australia

We report here new observations at 843 MHz of the galactic supernova remnant (SNR) G332.4+0.1 (Kes 32). They reveal what appears to be a fairly typical SNR, with a 'jet-like feature' emerging from it and expanding into an extensive 'plume' of low brightness emission. It is as though matter confined within the main body of the remnant has broken out through a nozzle and expanded into the plume. However, measurements at 8.4 GHz show the narrow part of the jet to have a relatively flat spectrum and no detectable polarization. Hence, if actually associated with the remnant, the feature is probably either a jet of particles from a central stellar remnant or a pre-existing gas structure ionized by the progenitor star.

The observations of G332.4+0.1 (Kes 32)¹ form part of a high-resolution, high-sensitivity study of SNR morphology using the University of Sydney Molonglo Observatory synthesis telescope (MOST)². At the declination of G332.4 (-60°) the telescope has a synthesized half-power beamwidth of 44 arc s (east-west) by 57 arc s (north-south). The effects of a -8%

The column headings are mass (M), radius (R), effective temperature (T_e), bolometric luminosity (L), age (t), central density (ρ_c), central temperature (T_c), and ratio (D) of total pressure to thermal pressure in the stellar interior.

Fig. 1 Contour and grey-scale representations of the 843-MHz radio emission from the SNR G332.4+0.1 (Kes 32) and the jet-like feature emerging from the north-east side of the remnant. Contour levels are: 38, 51, 65, 81, 100, 120, 150, 190, 230, 280, 340, 410 and 500 mJy per beam area.

sidelobe, intrinsic to the mapping process, are removed by cleaning³.

Figure 1 shows contour and grey-scale maps of the 843 MHz emission from the region of G332.4. The remnant is obviously a shell source—albeit irregular in outline and in emission intensity. The two brightest parts of the shell occur on the sides of lowest and highest galactic latitudes. The west rim of the SNR has an almost circular outline, with a weak point source near its centre. The east rim is less regular and the shell appears to have a small radius.

From a point of relatively weak rim emission on the north-east side of the SNR we see a jet-like feature emerging at an angle of $\sim 20^\circ$ to the galactic plane. Near the remnant the 'jet' is narrow, kinked and most intense, whereas further from the remnant the feature broadens to form a 'plume'. At the lowest levels of emission it is difficult to discern where the plume begins to blend with unrelated neighbouring emission.

Complementary observations at 8.4 GHz with the Parkes radio telescope (3 arc min beam) (Fig. 2) show the SNR to have a similar structure to that observed at 843 MHz, with a non-thermal spectral index, which varies over the source in the range -0.45 to -0.55 with an estimated error of 0.05. These measurements, also show the emission from the north-west and south-east rims to be linearly polarized at 8% and 3.5% respectively and at position angles near 135° and 0° . The 8.4-GHz observations extend over only the narrow part of the jet-like feature. A comparison of the two maps shows this part to have a spectral index of -0.05 ± 0.1 ; no polarization could be detected to a limit of $\sim 4\%$.

The distance to G332.4 is uncertain. A lower limit is suggested by the fact that it has no detectable optical or X-ray emission⁴, whereas RCW 103, a SNR some 30 arc min away is detected in these bands⁴; the distance to RCW 103 has been set at 3 kpc (ref. 5). An upper limit of ~ 7 kpc comes from a weak OH absorption⁶, and from the 'surface-brightness-diameter' relation⁷. We have adopted 5 kpc for the calculations that follow. At this distance the diameter of the SNR is ~ 25 pc, and its age, based on the standard Sedov expansion relations, is $\sim 5,000$ yr. On the assumption that the jet and SNR are associated, the narrow part of the jet is ~ 16 pc in length and ~ 3 pc in width. The projected distance from the SNR to the top of the plume is ~ 35 pc.

The association of the jet-like feature with the SNR rests most

strongly on the fact that its emission is strongest and narrowest at the point where it meets the edge of the remnant. The appearance of the jet strongly suggests a nozzle, with material from the interior of the remnant streaming out. However, we have misgivings about such an interpretation, because of the flat spectrum and lack of polarization in the jet, and because of the theoretical difficulty in constructing the rigid skin necessary for the nozzle formation. We have therefore explored two alternative models.

In the first model, we postulate that the jet and plume may comprise synchrotron radiating particles similar in origin and energy spectrum to those which make up the centrally-bright (Crab-like) components of SNRs such as CTB 80 (ref. 8) and G326.3–1.8 (ref. 9). The brightness of the jet implies minimum (equipartition) energy densities of the order of 10^{-10} erg cm⁻³ in the narrow section and a factor of 10 lower in the extended plume. The energetics of the jet do not appear to be a problem, but the collimation may be, given the small opening angle. One possibility could be a supercritical (thick) accretion disk surrounding the central source (see ref. 10); in an alternative scheme, proposed by Benford¹¹, the pulsar provides the collimation. We note, however, that there is no suggestion of a counter jet, whereas both these schemes are inherently symmetric. Further, because of the kinked nature of the jet, further external confinement seems likely. This may be provided by static pressure in the surrounding medium or by self-generated azimuthal magnetic fields, as suggested for the jet in the Crab nebula¹¹. Broadening of the jet and formation of the plume would happen at the point where confinement breaks down owing to the interaction of the flow with the surrounding medium.

The relatively flat spectrum in the narrow part of the jet would suggest that the relativistic particles are recent in origin and, like the centrally bright components of SNRs such as G326.3–1.8, have suffered little differential loss of higher-energy particles. This short time scale implies that velocities of the order of 10^4 km s⁻¹ in the jet itself are required for this material to be transported to the distances observed.

As a second hypothesis, we suggest that the feature might be thermal material. Here we envisage a neutral gas cloud, similar to those seen as extended, narrow (probably columnar) dark clouds, that has been ionized by the pre-supernova. If stellar UV emission were the only source of ionizing radiation, one

Fig. 2 Contours of the 8.4-GHz radio emission from G332.4+0.1. The contour levels are in increments of 105 mJy per beam area.

might expect recombination to take place after the SN event, with a typical recombination time of $\sim 3,000$ yr. However, the post-SN X-ray flux might be sufficient to significantly delay recombination. The stability of such a structure over the main-sequence lifetime of the ionizing star must be considered. A gas column originally in equilibrium with the surrounding interstellar medium in its cool neutral state could be expected to disperse when ionized on a time scale of $\sim 10^5$ yr.

We have also considered the possibility that the structure might have been shock-ionized following a breakout of the blast wave at a weak point on the shock boundary of the SNR. Such a model¹² has been advanced to explain the filaments which extend far beyond the apparent boundary of IC443. However, the shock would have to advance within the column at a mean velocity of at least four times the velocity of the main remnant shock, and this we view as unlikely.

Features associated with at least five other SNRs have been described as jets. On the smallest scale are the oppositely directed precessing radio jets associated with SS433 within the remnant W50. The radio emission is variable and extends ~ 0.03 pc from the central source in directions aligned with lobes of W50 (ref. 13). It is $\sim 10\%$ linearly polarized and has a spectral index near -0.6 .

A limb-brightened optical protrusion extending about 1 pc from the northern edge of the Crab nebula¹⁴ is most apparent in O III emission¹⁵. A radio counterpart has recently been detected¹⁶ at a level below 1% of the peak brightness of the nebula. This very weak radio feature is highly polarized and is thought to be non-thermal.

On a larger scale, two other remnants, CTB 37A (ref. 17) and CTB 80 (ref. 18), display radio features which we tentatively describe as jets. In the case of CTB 80, arc-like emission can be traced from a central bright core to an estimated distance of 30 pc from the remnant. In CTB 37A, the extended feature is aligned at right angles to the bright shell of the remnant. It is detached from the remnant proper and has the appearance of a misplaced section of shell. In both cases, the spectrum of the emission is distinctly non-thermal with an index not greatly different to that of the SNR.

None of these four jets closely resembles the feature near G332.4.

However, there is a feature associated with the SNR G5.3-1.0 (Milne 56)^{19,20}, which is similar in appearance to the jet and plume described here. The G5.3 jet appears to extend from a compact object out to a distance of about one source diameter, where it fans out into an immense plume. The jet shows no polarization. The plume in G5.3 is discernible to a much greater relative distance than the plume associated with G332.4, which is lost in the nearby confusion. We believe that the two objects fall in the same (SNR) category, and that, contrary to the suggestion of Helfand and Becker²¹, there is no need to invoke a new class of radio source.

Further high-resolution observations of the continuum polarization and of possible recombination line emission for the jet and plume apparently emanating from G332.4+0.1 are required to determine the emission process. New attempts to detect low-level X-ray emission, from either the jet or the postulated central source, would also be valuable.

The Molonglo Observatory is funded by the Australian Research Grants Committee, the University of Sydney Research Committee, and the Science Foundation for Physics within the university. We thank Professors B. Y. Mills and the late A. G. Little, and Dr J. M. Durdin for assistance in using the telescope also Professor D. B. Melrose and Dr G. V. Bicknell for useful discussions.

Spottiness in the large-scale structure of the microwave background

V. N. Lukash & I. D. Novikov

Space Research Institute, Academy of Sciences of the USSR, Moscow 117810, USSR

Barrow *et al.*¹ have recently considered the large-scale temperature variation ($\Delta T/T$) distribution of the microwave background in the open universe. Interest in this topic has been stimulated by new observations from balloons and the satellite Prognoz. Barrow *et al.*¹ seem to have misunderstood the theory that we have developed²⁻⁴ and arrived at conclusions directly contradicting our results. Here we argue that the main conclusions reached by Barrow *et al.*¹—that concerning the relationship between inhomogeneous and the most general homogeneous anisotropic cosmologies, and their other claim that the sky $\Delta T/T$ pattern of infinite-wavelength inhomogeneities is a superposition of Bianchi type VII models—are erroneous.

The angular pattern of $\Delta T/T$ over the celestial sphere has been called a 'spotty structure' due to the fact that the general form of the perturbation can be represented as a kind of Fourier integral. The basic functions of this expansion are akin to plane waves, and each of them produces a 'spot' (an annulus) in the $\Delta T/T$ pattern of angular size $\theta \sim \Omega = \rho/\rho_{cr}$ which is determined by the space curvature of the universe at the time of observation² (ρ is the total matter density). (In a spatially flat universe ($\Omega = 1$), the 'spot' is a quadrupole structure.) An important feature of ref. 2, distinguishing it from those discussed in the 1950s and 1960s⁵⁻⁷, is its close relationship to the geometry of homogeneous Bianchi type VII and V models. In this sense, the theory from ref. 2 is a generalization of the spot effect⁸⁻¹⁰ inherent in the Bianchi models mentioned above.

Arbitrary inhomogeneous transverse perturbations, which do not perturb the matter density, are directly related to the homogeneous anisotropic models. For these perturbations, one can always choose plane waves that are circularly polarized and consequently, permit the type VII group of motions. In this way, "... arbitrary vortex and gravitational-wave perturbations can be Fourier expanded into the homogeneous modes of type VII ...".² So, the celestial $\Delta T/T$ pattern of transverse perturbations of any scale is a linear superposition of Bianchi type VII spots. Just the opposite occurs with scalar (density) perturbations, the situation Barrow *et al.*¹ deal with.

Scalar waves are nonhomogeneous due to their longitudinal nature. That is why it is, in principle, not possible to relate density perturbations (even of large scale) to homogeneous models of any kind. This directly contradicts the claim by Barrow *et al.* that "... it is possible to model inhomogeneous universes close to the Friedman model as superpositions of the most general homogeneous Bianchi models ...". Nevertheless, the sky pattern of arbitrary scalar inhomogeneities is again a superposition of spots (but nonhomogeneous ones)²⁻⁴. The structure of these nonhomogeneous spots differs from the structure of spots in type VII models.

The angular size of a spot produced by a single scalar plane wave depends on the background space curvature only, and is independent of the perturbation scale, cosmological evolution, recombination dynamics, reheating, missing mass parameters and so on. (These factors determine the fine angular structure and the amplitude of the spot.) The large-scale shape of any spot is unique for all plane waves and can be easily derived using Lobachevski three-geometry (the space geometry of the open universe)^{4,10,11}:

$$\left| \frac{\Delta T}{T} \right| \sim \left(\frac{2\pi \tan \theta/2}{1 + (\pi \tan \theta/2)^2} \right)^2 \quad (1)$$

Here θ is the angle between the wave-vector and the line-of-sight, $\pi = \exp(-h\chi_r)$, h^{-1} is the curvature radius of the Lobachevski space, $\chi_r = \int_{t_0}^t dt/a$ is the geodesic three-distance of the observer (t_0) from the recombination sphere (t_r), $a = a(t)$ is the scale factor. For the euclidian space ($h = 0$) and equation (1) reduces to quadrupole dependence ($\sim \sin^2 \theta$). For the Lobachevski space $\pi < 1$ and all $\Delta T/T$ anisotropy develops inside the annulus of angular radius $\theta_0 = 2 \arctan \pi$ and width $\sim \theta_0$. For small Ω , $\pi \approx \Omega/4$ and the angular size of the spot is Ω . The large-scale profile, equation (1), of a single spot may already serve as an illustration of the effect of spottiness in open universes: for $\Omega = 1$ ($h = 0$) an arbitrary superposition of spots always results in a quadrupole distribution, while for $\Omega < 1$ ($h \neq 0$) a statistical distribution of $\Delta T/T$ with an angular correlation scale $\sim \Omega$ takes place. We now consider the fine structure of non-homogeneous spots.

The value of the wave-vector modulus k determines the fine structure of a spot, which actually consists of a number of narrow concentric rings packed inside the spot annulus. For $k > h$, the large-scale spot profile, equation (1), modulates the sequence of these rings. With decreasing k the rings inside the annulus smear out (the width of every ring increases) and the overall spot profile approaches equation (1) as $k \rightarrow 0$. The spot amplitude can be of any sign, so cold- and hotspots have equal probabilities.

In the infinite-wavelength limit ($k = 0$), plane waves do not perturb space curvature and become homogeneous—they exhibit the translational symmetry of type V models. [This is valid for all plane waves (not only for scalar ones). Recall that for the limit $k \rightarrow 0$, Bianchi type VII group of motions becomes type V. From the physical point of view, each of these models consists of three plane waves on the Friedman background with the wave vectors in the same direction: the scalar one with the infinite wavelength plus the vortex and the gravitational ones. The only difference between the two models is that in the type VII model the latter two waves have finite wavelengths (and are circularly polarized), while in the type V model they are infinite¹¹.] Thus, as was formulated earlier in refs 2-4, any infinite-scale perturbation is a superposition of type V models. This contradicts another conclusion of Barrow *et al.*¹ that infinite-wavelength scalar inhomogeneities are the superpositions of type VII models. The difference in conclusions means that the true cause of disagreement stems from the initial basic assumptions.

So, to analyse nonhomogeneous perturbations, we incorporate the Fourier expansion into the plane waves (which reduces to the well-known Fourier integral over e^{ikx} in the euclidian universe). Barrow *et al.*, in contrast, use the method of covering (piecewise smooth approximation) a nonhomogeneous solution with pieces (patches) of homogeneous models. They have developed their conception on the basis of an evolution formula for the density perturbations $\delta\rho/\rho$ in a dust-like medium (see their equations (16) and (17)). Such perturbations evolve in the same way for all wavelengths. Analogous expressions (with arbitrary functions of spatial coordinates replaced by constants) also exist in homogeneous models (see their equations (6) and (15)) which according to Barrow *et al.* enables one to approximate large-scale density perturbations in its most general form by "... an ensemble of homogeneous Bianchi VII models of differing density ...", that is with varying constants. Such an approximation over the entire spectrum is completely unjustified because homogeneous density perturbations originate from scalar waves with infinite wavelengths. At the same time, to invoke vortex and gravitational-wave modes (which perturb the curvature in type VII models) to calculate the shear evolution (see their equations (6) and (15)) is physically meaningless because we consider the density perturbations only. On the other hand, from the full Fourier integral, one infers that, when covering a large-scale density inhomogeneity with homogeneous patches of finite sizes, the dominant contribution will be due to the essentially nonhomogeneous modes with wavelengths of the order of the inhomogeneity size. The approximation of a nonhomogeneous solution with homogeneous ones is justified in the limit of infinite-wavelength perturbations only, but then it requires only type V models.

The analogy in the behaviour of homogeneous and nonhomogeneous scalar perturbations, based on the invariant evolution law for $\delta\rho/\rho$, cannot be extended to non-dust-like media, while the effect of spottiness is always there. It results from the global curvature of the universe ($\Omega < 1$)^{2,8} and depends only quantitatively on details of evolution.

We conclude by emphasizing that in the most general case, the spotty structure of $\Delta T/T$ in open universes is described by a Fourier integral and cannot, in principle, be reduced to an expansion in homogeneous Bianchi models. The discovery of a 'spotty' structure (or of its absence) of the microwave background would be extremely important for cosmology. It could answer basic cosmological questions such as what was the spectrum of primordial perturbations and what is the total density of all kinds of cosmic matter (including its invisible components).

Lukash and Novikov have given an interesting survey of their analyses of some of the features that may exist in the microwave background radiation in open universes. Here, we answer some criticisms that they make of our earlier analysis¹, and point out a further unusual feature that appears in the temperature distribution of the most general flat and open cosmological models.

Lukash and Novikov claim that in ref. 1 we erroneously represented infinite wavelength density perturbations by ensembles of Bianchi type VII universes at linear order, rather than by cosmological models of Bianchi types I or V, as required. This claim is incorrect. We found, and stated, that infinite-wavelength, pressure-free density inhomogeneities could be represented by ensembles of VII models only when one of their defining parameters, $x = h^{1/2}(1 - \Omega_0)^{-1/2}$, tends to infinity. In this limit, the type VII_h and VII₀ models specialize identically to the type V and I models respectively; here, Ω_0 is the density of the Universe today in units of the critical density and x or h is an arbitrary constant once Ω_0 is specified. (In the VII₀ case, the parameter x still exists when the limits $h \rightarrow 0$ and $\Omega_0 \rightarrow 1$ are taken simultaneously; see ref. 2 for details). Accordingly, all computations in ref. 1 of the effects of inhomogeneity on the background radiation were performed using the type I and V models, as Lukash and Novikov argue is necessary.

Finally, we would like to comment on one important difference between the hotspot patterns that arise in open universes of type VII and those arising in open universes of type V which were described by Lukash and Novikov and by ourselves¹. Although the type VII models are not relevant for the description of density inhomogeneities, they can describe the effects of gravitational waves and vorticity on the temperature anisotropy of the microwave background.

The general equation used by Lukash and Novikov to describe the hotspot structure is based on the type V paradigm where the spatial curvature is isotropic, and does not completely describe the most general hotspots generated by vortical and gravitational wave distortions; these will be described by the type VII_h behaviour rather than the simpler type V case. The geodesics in open type V universes exhibit focusing of a quadrupole temperature profile into a hotspot feature but with no change in the azimuthal coordinate of the geodesics propagating from their last scattering to the observer today. However, in type VII models there arises a geodesic spiralling effect which is superimposed on the hotspot structure. This feature was first noted by Collins and Hawking³ and its observational effects are examined in detail in ref. 2. Figure 1 shows examples of the temperature anisotropy patterns predicted in VII₀ and VII_h universes. In the VII₀ case, where $\Omega_0 = 1$, there is a pure quadrupole plus the geodesic spiralling effect, whereas in an open VII_h model with $\Omega_0 = 0.7$, we see a spiral plus quadrupole pattern focused into a spiral hotspot. The number of turns of the spiral is inversely proportional to the parameter x . In the limit $x \rightarrow \infty$, in which case the spatial curvature becomes isotropic, the VII₀ and VII_h models become those of types I and V again, the spiral effect disappears and we recover either a quadrupole or the

Fig. 1 Microwave background temperature profiles, $T(\theta_0, \phi_0)$, predicted in the region of observed angles $0 < \phi_0 < 2\pi$, $\pi/2 \leq \theta_0 < \pi$. The radial distance represents the magnitude of $T(\theta_0, \phi_0)$. We assume that the last scattering of the photons occurred at a redshift of 1,000, and the anisotropy amplitude is taken to be the maximum allowed by current observations. *a*, Spatially homogeneous-type VII₀ cosmological model with $x=0.067$ and $\Omega_0=1$. *b*, An open spatially homogeneous cosmological model of type VII_h with $x=0.067$ and $\Omega_0=0.7$. In *a*, the pattern is approximately a pure quadrupole modulated by the geodesic spiralling effect. In *b*, both the quadrupole and spiral patterns seen in *a* have been focused into a region of smaller angular scale towards the axis $\theta_0 = \pi$ by the negative spatial curvature. The result is a spiral hotspot. The spirals are left-handed in the observed angles. As $x \rightarrow \infty$ the spiral effect disappears and the hotspot in *b* degenerates into the simple variety found in the type V models, and *a* becomes the pure quadrupole of type I. For further details and discussion see ref. 2.

simple hotspot structure discussed in the preceding letter and ref. 1. Note that because this spiral feature does not arise in closed universes, it may enable observers to determine whether the Universe is open or closed, no matter how close its density lies to the critical value².

We thank J. Stein-Schabes and N. Kaiser for comments and V. Lukash and I. Novikov for communicating their results before publication. D.H.S. and R.J. acknowledge financial support at Sussex from the SERC.

A search for evidence of nuclearites in astrophysical pulse experiments

N. A. Porter*, D. J. Fegan*, G. C. MacNeill*
& T. C. Weekes†

* Physics Department, University College, Dublin 4, Ireland

† Harvard-Smithsonian Center for Astrophysics, Whipple Observatory, Arizona 85645-0097, USA

De Rújula and Glashow¹ have suggested that nuclearites, aggregates of up, down and strange quarks in roughly equal proportions, may form a component of the material reaching the Earth from the Galaxy. On traversing the atmosphere they will look something like meteors, but will travel faster. The masses of these aggregates may vary over a wide range and their velocities will be typically 250 km s^{-1} , corresponding to the Sun's galactic rotation. If all the dark matter in the Galaxy is assumed to be in the form of nuclearites, a limit can be set to the incoming flux. We report here upper limits derived from four experiments, originally carried out to detect cosmic γ rays, as well as some derived by other authors, which would be sensitive to pulses of light from nuclearites in the lower atmosphere. Our upper limits are compatible with the suggested maximum flux and competitive with a search for tracks etched in mica², which could also be caused by nuclearites.

De Rújula and Glashow show that the visual magnitude of an atmospheric nuclearite:

$$M = 10.8 - 1.67 \log_{10} (m/10^{-6}) + 5 \log_{10} (h/10 \text{ km}) \quad (1)$$

where m is the mass of the nuclearite in grams and h its distance from the detector. The nuclearite will radiate predominantly in the lower atmosphere, effectively below:

$$h_{\text{max}} = 2.7 \text{ km} \ln (m/1.2 \times 10^{-5} \text{ g}) \quad (2)$$

In our experiments, m ranged from 10^{-3} to 10 g, and h_{max} was typically 20–30 km, except in one case where it was constrained by the arrangement of the optical system.

The first five experiments that we consider were carried out at the Whipple Observatory, Arizona. The first³, in 1969–72, used the 10-m reflector to search for γ rays from the Crab Nebula or, for pulsars in the 10^{11} -eV region. A total of 112 h of observation were taken at various zenith angles. To trigger the system, ~ 50 photoelectrons were required in an integration time of 10^{-8} s. In a subsequent analysis⁴, a search was made in the data for bursts of events lasting up to 0.1 s. This analysis is the basis of the present discussion; 12 events were required to constitute a burst. The transit time through the field at a typical detectable height was $\sim 10^{-2}$ s. To produce 12 events from random fluctuations in 10^{-2} s, with a basic integration time of 10^{-8} s, requires about a 4.5σ upward deviation from the mean light of the nuclearite in these 10^{-8} s intervals. (The night-sky background contribution⁵ was small, $\sim 10\%$ of that from the nuclearite). Fifty photoelectrons are needed, σ therefore is 11.1, and $\sigma^2 = 123$, the mean number of photoelectrons per 10^{-8} s interval. With a 15% photocathode efficiency at the photomulti-

Fig. 1 Mass of the nuclearites plotted against incoming flux. The sources are detailed in Table 1.

plier, we obtain a photon number of 823 photons in 10^{-8} s average illumination over the 10^{-2} s transit time. The area of the reflector was effectively 60 m^2 , leading to a flux of 1.37×10^{-3} photons cm^{-2} in 10^{-8} s, or 1.37×10^5 photons $\text{cm}^{-2} \text{ s}^{-1}$. Converting this to $\text{erg cm}^{-2} \text{ s}^{-1}$ to obtain the visual magnitude⁶ and taking $0 \text{ mag} = 8.5 \times 10^{-6} \text{ erg cm}^{-2} \text{ s}^{-1}$, we obtain a limiting magnitude of 3. Combining equations (1) and (2) the mass became 0.16 g , h_{max} was 25 km , and a typical distance h was 15 km .

The surface area of the conical frustum from 2.2 km (altitude of observatory) up to 25 km at a mean zenith angle of 25° and full field of view 1° was 16.6 km^2 . Upward moving nuclearites occur for this mass, so the whole area is effective. The statistical upper limit, at the 99% level, from the burst analysis, was $477 \text{ events yr}^{-1}$. We therefore obtain an upper limit flux of $28.7 \text{ events km}^{-2} \text{ yr}^{-1} (2\pi \text{ sr})^{-1}$, at a mass $m = 0.16 \text{ g}$. This limit is plotted as a in Fig. 1, the diagonal line is the upper limit to the cosmic flux, derived by De Rújula and Glashow on the assumption that the entire dark matter of the Galaxy consists of nuclearites. The triangular area in Fig. 1 represents the limits derived in ref. 1 from an experiment by Price *et al.*² using the etching of tracks in buried mica samples, originally intended for the detection of monopoles. It will be seen that our limit falls below the maximal flux and is compatible with the mica experiment.

We are aware of eight other experiments which can be similarly analysed. Their main features are summarized in Table 1 and the resultant flux limits plotted in Fig. 1.

The results are generally comparable with those obtained in the mica experiment. Only that of Ogelman¹⁴ can confidently be placed below both the maximal flux and the mica limit. Experiments designed specifically for nuclearite detection could, however, significantly reduce the limits by optical techniques.

Table 1 Cosmic flux limits for nuclearites of various masses

Ref.	Mirror diameter (m)	Mass (g)	Flux limit (events $\text{km}^{-2} \text{ yr}^{-1} (2\pi \text{ sr})^{-1}$)	Point in Fig. 1

Three-dimensional icosahedral symmetry has been reported¹ for an alloy consisting of aluminium with 14 atomic% manganese. The electron diffraction patterns appear consistent with a three-dimensional Penrose tiling² or quasi-lattice^{2,3}, although one report has suggested a 20-fold multiple twinning of a close-packed structure⁴. Clearly, however, the determination of the reciprocal lattice is only a first step; it is a further problem to determine the atomic motif(s) required to complete the structure. High-resolution electron microscope images of this alloy, reported here, reveal the localized pentagonal pseudo-symmetry of the structure and show that it projects as a two-dimensional Penrose tiling^{2,5}. A structural model is derived, based directly on the experimental images and an analysis of the polyhedra occurring in the crystallographic phase Al_6Mn .

The specimen was provided through the courtesy of Dr Leo Bendersky (National Bureau of Standards, Washington, DC) and was prepared as described in ref. 1. Figure 1 shows a view, looking exactly along one of the 5-fold symmetry axes, of an area considerably less than 100 Å thick. The imaging conditions in the JEOL-200CX instrument used were chosen so that, according to the usual theories of image contrast⁶, we would expect the areas of black contrast to represent regions of relatively high atomic density, at a resolution of ~2.4 Å. There is a striking resemblance to the original Penrose drawings of tiling patterns⁷. The enlargement in Fig. 2a shows a pronounced localized 5-fold pseudo-symmetry, the centre of which maps almost perfectly onto one of Penrose's drawings (Fig. 2b). In general, the pentagonal symmetry is short-range, rarely extending further than 15 Å, as expected for Penrose tiling. Rotation of the electron micrograph with respect to a fixed glancing angle reveals five interpenetrating sets of spacings in the ratio 1:τ ($=1+\sqrt{5}/2$), characteristic of the Fibonacci series. Note also the decagonal rings (diameter 14.5 Å) of white spots, pentagonal stars of white spots (separation 5.4 Å) and the decagonal and pentagonal rings of black contrast (diameters 8.8 and 5.4 Å, respectively). These are shown schematically in Fig. 2c, which also allows the five Fibonacci sequences comprising this area to be identified.

Following the idea of Mackay², we tried to build a structural model using acute and obtuse rhombohedral units, taking the rhombic edge to be 2.7 Å (the mean Al-Al separation in crystalline aluminium). Although some features of the image could be matched, for example the decagonal rings of black contrast correspond geometrically to the projected waist of Mackay's rhombic triacontahedra, we could not match the diameters or disposition of the small dark rings on either the larger decagonal rings of white spots or the pentagonal stars of white spots. We conclude that the structure is not based on such slightly distorted elements of cubic close-packing, at least if the white spots represent relatively low densities of atoms. It appears that, in this case, we must search for a different structural motif for the quasi-lattice.

A careful consideration of the structure reported⁷ for Al_6Mn reveals (Fig. 3a) that it may be considered as a stacking of two symmetrically equivalent layers composed of polyhedra which differ from an icosahedron only in that one vertex is unoccupied (Fig. 3a inset). These truncated icosahedra (or TICOS) share edges within layers (Fig. 3b) and corners between layers (Fig. 3c). Note that each TICOS contains: one Mn atom not shared with adjacent polyhedra; eight Al atoms, shared between those TICOS within layers; two Al atoms, shared with one other

Fig. 3 [001] Projection of crystalline Al_6Mn , showing edge-sharing of truncated icosahedra (TICOS) within layers and corner-sharing between layers. Each TICOS contains one Mn atom (on surface) and one Al atom (internal) which are not shared with adjacent TICOS, the eight remaining Al atoms being shared between two TICOS.

TICOS in adjoining layers; and a further Al atom inside each TICOS, which is therefore unshared. The net result is, of course, a stoichiometry of Al_6Mn .

This analysis suggested that the observed Penrose tiling could be explained by a cooperative rearrangement of TICOS. Figure 4 shows two levels of a model for the central area of Fig. 2. The pentagonal star at the first level is surrounded by decagonal rings composed of rings of five TICOS at both first and second levels, tessellated according to the observed tiling pattern. The model could readily be extended, at least in two dimensions, to match details of the dark (and white) contrast variations in the experimental images. Note that the algorithm used was that a white spot represents the centre of a column of TICOS along the projection axis. Also, there is a relatively low density of Al atoms inside the TICOS, Mn always occupying asymmetrically coordinated sites on the pentagonal rings at the surface of individual TICOS. The stoichiometry Al_6Mn is preserved in this model, since on average each TICOS retains the same number of shared Al atoms (8) and unshared Mn (1) and Al (1) atoms.

The essential icosahedral geometry of the TICOS gives us some confidence, justified so far by model-building, that a fully three-dimensional model may be achieved in which six such interpenetrating two-dimensional networks coexist. Dark-field observations suggest correlation lengths of ~ 50 – 100 Å along the 5-fold axes. Consideration of the configurations of black and white contrasts expected for overlapping in projections of the possible two-dimensional patterns has so far been consistent with the experimental images. We are now investigating whether existing electron dynamical techniques can be used to calculate the images, and it should be possible to calculate images for appropriate sections of the model using existing techniques for non-periodic objects⁸.

The experimental observations have already been extended to both 3-fold and 2-fold axes. Pseudo-symmetric centres are again observed. In addition, stacking faults and other defects occur in the quasi-lattice (sight along the dark fringes in Fig. 1);

Fig. 4 Assemblage of TICOS polyhedra to generate two-dimensional Penrose tiling reproducing the central area of Fig. 2. TICOS were placed at the centre of each white spot in the experimental image.

localized areas appear to transform to less-ordered (glassy) states and the crystalline phase may also occur (L.A.B. and P.J.L., in preparation).

The structural principles described above, which we believe to be justified reasonably well by both the experimental images, and our analysis of the structure reported for Al_6Mn , should be regarded as tentative. Nevertheless, we hope they will provide a realistic basis for future studies of the alloy's structural and physical properties. What is most intriguing, of course, is whether we are concerned with a material having singular structural properties because of the chemistry of Al and Mn, or whether the principles suggested by the quasi-crystal concept will find more widespread application. We favour the latter possibility.

Quantization effects in the photoelectrochemistry of superlattice photoelectrodes

A. J. Nozik, B. R. Thacker & J. M. Olson

Solar Energy Research Institute, Golden, Colorado 80401, USA

Size quantization effects have created much recent interest. In solid state physics, for example, the novel effects exhibited by thin layered semiconductor structures in the form of multiple-quantum-wells (MQW) or superlattices (SL) are under intense study^{1–7}. In photoelectrochemistry, quantum-size effects produced by very small (<100 Å) semiconductor particles have been analysed^{8–11}. We report here the first quantum size effects produced in a photoelectrochemical system using a superlattice photoelectrode. The electrode contained 40 alternating layers of undoped GaAs and $\text{GaAs}_{0.5}\text{P}_{0.5}$ each 250 Å thick. This structure produces a strained-layer superlattice (SLS) with 20 GaAs quantum wells having a well width of 250 Å; the $\text{GaAs}_{0.5}\text{P}_{0.5}$ barrier widths are also 250 Å thick. The barrier heights for electrons in the conduction band

and for holes in the valence band for this SLS are 0.28 eV and 0.30 eV, respectively⁶. The photocurrent-wavelength response shows remarkable structure at room temperature that arises from the presence of discrete energy levels in the GaAs quantum wells. This structure is readily resolvable into multiple photocurrent peaks that are in excellent agreement with theoretical predictions of the discrete energy levels in the quantum wells. These results have important implications for photoelectrochemical energy conversion and for the characterization and analysis of SL and MQW structures in general.

The SLS structure was grown by metal-organic chemical vapour deposition (MOCVD) using continuous flows of trimethylgallium, PH_3 , and AsH_3 . The growth rate and growth temperature were $0.1 \mu\text{m min}^{-1}$ and 750°C , respectively. A $10\text{-}\mu\text{m}$ $\text{GaAs}_{1-x}\text{P}_x$ buffer layer graded from $x=0$ to 0.25 in five equal steps was inserted between the $\text{p}^+\text{-GaAs}$ substrate and the SLS structure. The $\text{p}^+\text{-GaAs}$ wafers were oriented 2° off (100) towards (110) and were cleaned before growth using a 6:1:1 $\text{H}_2\text{SO}_4:\text{H}_2\text{O}_2:\text{H}_2\text{O}$ etch. The SLS layers are not lattice-matched and large strains are, therefore, generated in the layers both parallel (biaxial shear strain) and perpendicular (hydrostatic strain) to the layers^{5,6}. A scanning electron micrograph (SEM) of the layered structure is shown in Fig. 1; the large strain results in wavy, but equidistant, layers. The top layer is GaAs. The SLS structure studied in this work has the same configuration as that reported by Gourley and Biefeld⁶ to exhibit quantization effects in optical and photoluminescence data.

The theoretical energy-level scheme for a $250 \text{ \AA}$ $\text{GaAs}/\text{GaAs}_{0.5}\text{P}_{0.5}$ SLS is shown in Fig. 2. The energy-level calculation is a simple modification of that previously reported⁶ and includes the effects of lattice strain. The selection rules for optical transitions in quantum wells require that $\Delta n=0$, where n is the quantum number of the respective valence and conduction band states. The allowed transitions are indicated in Fig. 2.

Photoelectrodes were prepared from the SLS wafer by contacting the $\text{p}^+\text{-GaAs}$ substrate with a gold ohmic contact and sealing all but the front SLS surface with epoxy; the electrodes were then immersed in an electrolytic cell containing either 0.2 M ferricyanide in 1 M H_2SO_4 or 0.1 M Eu^{3+} in 1 M HClO_4 .

Photocurrent action spectra (quantum yield plotted against wavelength) at room temperature are shown in Fig. 3 for two different samples of the original SLS wafer in the $\text{Eu}^{3+}/\text{HClO}_4$ electrolyte; the electrode potential was held at -0.8 V (versus SCE) and the photocurrents were cathodic. A remarkable feature is the clear presence of photocurrent peaks in the spectra; conventional GaAs photoelectrodes in the form of single crystals or thick single layers deposited by MOCVD were examined and showed the usual photocurrent onset at the band edge of GaAs followed by a smoothly increasing monotonic photocurrent that saturates to a constant value at $\sim 875 \text{ nm}$. The experimental data for the superlattice photoelectrode could be fitted extremely well by a sum of seven gaussian peaks constrained to a common

linewidth. The peak positions and heights are indicated in Fig. 3. The data could be fitted equally well using an eV scale rather than wavelength. In the former case, the fitted linewidth value was 50.6 meV.

The data show that the peak positions for photoelectrodes prepared from different regions of the SLS wafer are the same, while the peak intensities vary. We believe that the various peak intensities reflect electron transfer into the electrolyte from the discrete levels in the quantum wells. If the electrons were being injected into the electrolyte only from the lowest quantum level, then the relative peak intensities would be constant for a given quantum well geometry. Also, the observed photocurrent spectra are not consistent with that expected for absorption into the discrete levels³, followed by relaxation to and charge transfer from the lowest state. Thus, Fig. 3 shows that the SL layers are of uniform thickness, but the electron transfer probability from the discrete levels vary with position in the sample. This result is consistent with the SEM pictures (Fig. 1) showing uniform layer thicknesses but irregular outer surface layers; the outer surface in contact with the electrolyte will control the electron transfer kinetics.

Support for electron transfer from the higher lying states in the quantum well comes from the observation that the higher energy photocurrent peaks ($680 < \lambda < 750 \text{ nm}$) show markedly lower relative intensities compared with the lower-energy photocurrent peaks when a lower lying (more positive in the SCE scale) redox couple, such as ferricyanide, is used instead of Eu^{3+} . This effect is attributed to the poorer overlap of the higher lying levels in the conduction band quantum well with the energy levels in the electrolyte.

The experimental photocurrent spectra agree very well with the first six allowed ($\Delta n=0$) transitions shown in Fig. 2. The seventh experimental peak at 1.77 eV fits to a non-allowed, $\Delta n=1$ transition from the $n=7$ level in the valence band to the $n=6$ level in the conduction band; this is labelled transition 6' in Fig. 3. Non-allowed, $\Delta n=1$ transitions have also been seen in SLS optical data⁶.

As seen in Fig. 3, the photocurrent response has a maximum at $\sim 750\text{--}780 \text{ nm}$, and then falls to nearly zero at wavelengths $< 680 \text{ nm}$; in this sample the response remained near zero down to 400 nm . This drop-off in photocurrent below 750 nm is, of course, highly detrimental to good solar conversion efficiencies in photoelectrochemical devices. However, we believe this drop-off is not an intrinsic characteristic of superlattice or MQW electrodes; other samples do not show this behaviour. A possible explanation is that the higher energy photons are absorbed closer

Fig. 1 SEM photograph of SLS cross-section; outer surface is at top. Wavy layers reflect strain from lattice mismatch.

Fig. 2 Theoretical energy level scheme for $\text{GaAs}/\text{GaAs}_{0.5}\text{P}_{0.5}$ strained-layer superlattice (SLS). Allowed transitions ($\Delta n=0$) are shown, along with a non-allowed transition ($\Delta n=1$) from $n_h=7$ to $n_e=6$. The theoretical transition energies are compared with the experimental values. CB, conduction band; VB, valence band.

Fig. 3 Photocurrent-wavelength spectra for GaAs/GaAs_{0.5}P_{0.5} SLS. *a* and *b* represent two different regions of the SLS wafer. Solid lines, theoretical fits to seven gaussian lines with equal linewidths

to the outer surface of the SLS, where the layer distortions and strains are greater (see Fig. 1), and hence suffer faster e^-h^+ recombination rates.

The quantum efficiencies exhibited by the present sample are consistent with electron diffusion lengths of the order of 0.05 μm . As expected, this is much lower than the values of 1–2 μm for bulk GaAs or for diffusion parallel to the superlattice layers¹². The lower values for the perpendicular direction are caused by inhibition of charge transfer by the GaAs_{0.5}P_{0.5} barriers. Significant penetration through the relatively thick barriers could be attributed to enhanced tunnelling created by strain-induced defect states in the barrier. Another possibility is that thermionic emission processes may have a role. Further work is required to understand these results more completely.

The good resolution of the photocurrent spectra even at room temperature is surprising; optical absorption and emission experiments are usually done at low temperatures to produce good spectral resolution. Further experiments as a function of SL composition, well and barrier dimensions, and temperature are in progress.

The ability of MQWs and SLs to absorb light at discrete quantum levels and permit charge transfer from these levels provides a potential mechanism for achieving the high theoretical thermodynamic conversion efficiencies predicted for hot carrier injection processes¹³. This is because carrier relaxation to the semiconductor band edges (defined for bulk material), with its attendant thermal loss, is inhibited by the presence of discrete energy levels with relatively large separation.

We thank Bruce Parkinson, Mark Spitler, and John Turner for stimulating discussions; Don Williamson of the Colorado School of Mines for computer fitting experimental data; Mowafak Al-Jassim and Kim Jones for SEM pictures; and Tim Gessert for technical assistance. This work was funded by the US Department of Energy, Office of Basic Energy Sciences, Division of Chemical Sciences; J.M.O. was supported by the DOE Photovoltaic Energy Technology Division.

Double seismic zone in Tonga

Hitoshi Kawakatsu

Department of Geophysics, Stanford University, Stanford, California 94305, USA

The clear evidence of a double seismic zone beneath Japan^{1,2} has led seismologists to search for other such zones elsewhere. Because they have been found in few other areas^{3–6}, double seismic zones are thought to be rare and to depend strongly on a peculiar combination of external conditions (such as age of the descending slab, and the convergence rate)⁷. We report here a new double seismic zone which has been found beneath the Tonga arc⁸, where the stress state in the subducting slab has been described as strongly down-dip compressional^{7,9,10}. This discovery suggests that the double seismic zone is a general feature of subducting slabs and may be found in many other subduction zones.

A double seismic zone is a zone of double-planed activity of intermediate depth earthquakes in the subducting lithosphere, usually extending from 60 to 180 km depth (Fig. 1). The two planes are generally separated by $\sim 40 \text{ km}^{1,2,11}$ at the shallow end and gradually merge at depth. The focal mechanisms of earthquakes in the upper and the lower planes tend to have compressional and tensional axes in the direction of the dip of the subducting slab, respectively¹. Double seismic zones have been reported in Tohoku, Japan^{1,2,12,13}, Kuril and Kamchatka^{3,14}, eastern Aleutians^{5,6} and Peru⁴. There have also been suggestions of double seismic zones in the central Aleutians¹⁵ and Marianas¹⁶, but the evidence is not conclusive^{7,17,18}.

Figure 2 shows a view of the general seismicity in the Tonga region with some tectonic features. The deeper portion ($> 300 \text{ km}$) of the slab has a high level of seismic activity and a down-dip compressional stress (or strain) state inferred from the earthquake focal mechanisms^{10,19,20}. This has led to conclusions that the slab cannot penetrate into the lower mantle in this region^{19,20}. It has also been suggested that the stress state of the intermediate depth range of the subducting slab under the Tonga arc is strongly down-dip compressional^{7,9,10}. Isacks and Molnar⁹ state that "a compressional stress is transmitted through nearly all parts of the slab". Even after the discovery of a clear double seismic zone in Japan, neither Billington¹⁰ nor Fujita and Kanamori⁷ hinted at the possibility of a double seismic zone in the Tonga region, although they identified one event which shows down-dip tension at a depth of 186 km. However, a careful examination of the mechanisms and depths of earthquakes reveals that there are several down-dip tensional events in this region. They are located consistently deeper than and seawards of the down-dip compressional events, suggesting the presence of a double seismic zone.

Figure 3 clearly suggests the presence of a double seismic zone from a depth of $\sim 60 \text{ km}$ to $\sim 200 \text{ km}$. This region (azimuth 109° to 116°) was chosen because both the geometry of the subducting plate (inferred from seismicity) and the focal mechanisms suggest that the deformation of the slab occurs in a simple two-dimensional manner⁸. North of azimuth 109° ($\sim 17.5^\circ \text{ S}$), the end of the subduction zone results in hinge faulting, introducing more complicated stress and strain structure in the slab. South of azimuth 116° ($\sim 24.5^\circ \text{ S}$), the lateral bend of the slab near 26° S prevents a simple two-dimensional view of the subduction process.

Cross-sections with narrower azimuth ranges (every 1° along the strike of the trench)⁸ including smaller events show that the down-dip compressional and tensional events are consistently located on the upper and the lower edge of the zone of seismicity, respectively, in every section. The result of relative relocation (Fig. 4) supports the presence of a double seismic zone. The down-dip tensional events in Figs 3 and 4 are consistently located seaward of and below the down-dip compressional events, exactly as expected for a double seismic zone.

Fig. 1 Double seismic zone beneath the northern Honshu arc, Japan (after ref. 1). The precise determination of the microearthquake hypocentres using data from the seismic network of Tohoku University revealed a clear separation of two seismic zones. The figure is vertically exaggerated by a 2:1 ratio.

What are the implications of this discovery of the double seismic zone beneath the Tonga arc? First, the double seismic zone is a rather persistent feature of subducting slabs. Tonga has the most active deep seismicity but the compressional strain (due either to inability of the slab to penetrate into the lower mantle^{19,20} or to the strong viscous resistance to the subduction in the mesosphere⁹) transmitted from below 200 km depth cannot overprint and erase the pre-existing double seismic zone. On this basis, I predict that there is also a double seismic zone beneath the Izu-Bonin arc, even though it has active deep seismicity and down-dip compressional stresses. Furthermore, I speculate that a double seismic zone will be observed in most subduction zones (at least in those areas where both down-dip compressional and tensional events are already observed^{7,9}). The observation of double seismic zones has been prevented by the lack of high-quality local networks in most subduction zones and the fact that the time span of reliable observations of earthquake focal mechanisms is too short. It has also been difficult to distinguish shallow (<80 km) down-dip tensional events from shallow-angle thrust faulting events, which are very common in subduction zones, without detailed wave-form analysis. This is because they have similar focal mechanisms and the reported depths (obtained by the International Seismology Centre (ISC) or by preliminary determination of epicentre) of shallow events are not reliable. A systematic analysis of these events, which can now be undertaken through the Global Digital Seismograph Network²¹⁻²³, will help to identify more down-dip tensional events.

Second, this discovery constrains possible mechanisms for the origin of the double seismic zone. It excludes geometrical sagging^{24,25} as a possible mechanism since the strong down-dip compressional strain transmitted from below 200 km could easily overprint strain features caused solely by sagging. The simple geometrical unbending^{15,16,26} with a brittle-plastic rheology suggested by Tsukahara²⁶ seems to be the best description of the physical mechanism of the double seismic zone.

Above a depth of ~60 km, oceanic lithosphere bends downwards when it subducts into the mantle. The fact that the subducting lithosphere appears to be straight in the mantle below a depth of ~200 km indicates that the lithosphere must unbend in a depth range from ~60 to ~200 km to become straight below a depth of ~200 km. A simple geometrical argument shows that the strain rate due to this unbending is of the order of 10^{-15} to 10^{-14} s^{-1} above a depth of ~100 km where most of unbending is taking place and is high enough to account for all the energy released by earthquakes of the double seismic zone⁸. Even below a depth of ~100 km where the slab appears to be straight, the

Fig. 2 Schematic view of the general seismicity of the Tonga subduction zone. The depth-constrained ISC events are plotted with tectonic features. The broken line represents the trench. The lines perpendicular to the trench are parts of the great circles which pass through the pole of the arc and the numbers denote the azimuth of the great circle measured clockwise from the north at the pole of the arc. The pole of the arc is located at 20.6° N , 102.8° E , so that the 100-km isodepth contour of Isacks and Barazangi⁴ is 90° distant away from the pole. The two lines parallel to the strike of the trench are at the distances 87.5° and 92.5° .

Fig. 3 Cross-section perpendicular to the trench. All the intermediate-depth (60 to 350 km) events occurring between azimuths 109° and 116° for which focal mechanisms are available, are plotted: ●, Down-dip compressional; ○, down-dip tensional events; ×, events which are not either compressional or tensional. The small circles are events for which only the type of the mechanism can be determined⁸. The depths are all constrained by pP-P times reported with ISC. For the down-dip tensional events, depths are also checked by WWSSN seismograms. For events shallower than 200 km, the near side of the focal sphere is also plotted. Event 1: the depth (61 km)²³ of this large ($M_0 = 1.4 \times 10^{28} \text{ dyn cm}$)²³ normal fault event (22 June, 1977) is controversial²³. The aftershock distribution³⁰ and the excitation of overtone surface waves (E Okal, personal communication) seem to suggest that the faulting extended deeper than 100 km. Thus, the depth given here is probably the shallowest estimate.

unbending strain rate can easily be of the order of 10^{-17} to 10^{-16} s^{-1} (an unbending strain rate of 10^{-17} s^{-1} of a 100-km thick slab, subducting 10 cm yr^{-1} , corresponds to a change of the dip angle of $\sim 0.05^\circ/100 \text{ km}$, which is impossible to detect from seismicity⁸). On the other hand, the strain rate due to thermo-elasticity^{27,28} (10^{-18} to 10^{-17} s^{-1})²⁸ is too low to be the main cause of the double seismic zone. Although all the other proposed mechanisms may contribute to its occurrence, the double seismic zone can be satisfactorily explained by the simple

Fig. 4 To assign appropriate relative errors to the hypocentral parameters, a relative relocation was performed⁸. The method is similar to one used by Samowitz and Forsyth¹⁶, except that here only depth constrained events are used. Data are selected from the ISC bulletin from 1971 to 1979 with the following conditions; pP-P constrained depths between 60 and 200 km, >30 P arrival observations. For the first iteration, all events are relocated with the depths fixed at the pP-P depths using the P-wave arrival times reported at stations between 30° and 100° distance and ISC locations as the starting guesses; 440 stations were used. After the first iteration, the stations which have arrivals from >10 earthquakes are selected and assigned station adjustments as a linear function of distance between stations and earthquakes by the least squares method. This leaves 113 stations. For the second iteration, travel times are first adjusted by using the station adjustments estimated in the first iteration. Each event was then relocated separately using only the arrivals from those 113 stations. The estimated relative errors (90% confidence intervals) are usually smaller than the largest circles. Symbols are as in Fig. 3. The smallest circles denote events for which no information about their focal mechanism is known. Although a clear separation of two seismic zones seems to exist, it could be coincidence¹⁷. Therefore, what is most important is that the down-dip compressional events are still always located above the down-dip tensional type events even after the relocation.

model of geometrical unbending. The cause of this unbending is uncertain and probably varies from place to place. For example, pressure due to mantle flow²⁹ (or equivalently, dynamical sagging²⁵) or the weight of the slab itself can unbend the slab.

For a given magnitude of the strain rate, the distance between the two seismic zones depends strongly on the rheological properties and the thermal structure of the descending lithosphere²⁶. Thus, as pointed out by Tsukahara²⁶, studies of the fine structure of double seismic zones in many areas will give important new information on the thermal and rheological properties of the subducting lithosphere⁸.

I thank Bob Geller, Eric Peterson, Rick Schult and Norm Sleep for reviewing the manuscript. Comments by Drs Klaus Jacob and Bob Engdahl also improved the manuscript. This work was supported by NSF grants EAR82-18961 and EAR83-06555.

The composition of volcanic rocks erupted in complex plate tectonic settings can provide information on the nature of the underlying mantle. We show here that the geochemistry of alkali basalts from Japan and eastern Asia varies systematically with distance from the Japanese island-arc. Samples from northeastern Japan, relatively close to the Japan Trench, are enriched in K, Sr, Ba and Rb and depleted in Ta, Nb and Ti as compared with samples from southwestern Japan. Both sets show an island-arc influence on their composition, but alkali basalts from still further west (Korea and northeastern China) have chemistries which are indistinguishable from ocean island basalts. We suggest that the north-eastern island-arc type of alkali basalts were derived from a 'normal' upper mantle source altered by fluids or melts released from the underlying subducted Pacific plate. The extent of this island-arc-related alteration decreases with distance from the trench.

Major and selected trace-element concentrations of 200 Tertiary to Recent alkali basalts were determined by a combination of X-ray fluorescence (XRF) and instrumental neutron activation analysis (INAA) using the method described by Barnes and Gorton¹. Most of the samples analysed are nepheline normative and have the following characteristics: SiO₂ contents of less than 52 wt%, Ni contents of greater than 100 p.p.m., Cr contents greater than 150 p.p.m. and no detectable Eu anomalies. Samples with these characteristics are assumed to have retained their primitive chemistry. Olivine ± clinopyroxene fractionation may have produced a slight increase in the concentration of the incompatible elements in some samples but any change in ratios of these elements will be small.

Selected analyses are plotted on normalized abundance pattern (NAP) diagrams²⁻⁵ (Fig. 1). These diagrams give the concentration of selected incompatible elements normalized to their concentration in the primitive mantle. The elements are arranged systematically in order of increasing incompatibility, with the most incompatible elements plotted on the left. Figure 1a gives NAPs for an average depleted mid-ocean ridge basalt^{3,4}, typical Hawaiian tholeiite⁶ and alkali basalt⁶, an average continental alkali basalt from Kenya⁷, an average island-arc calc-alkaline basalt⁴ and an average arc tholeiite⁴. Both island-arc rock types are characteristically enriched in K, Ba, Sr and Rb and depleted in Ta, Nb and Ti (weakly) relative to adjacent elements in the NAP diagram.

NAP diagrams for samples from Rishiri Island (northeastern Japan), southwestern Japan, Jejudo Island (Korea) and Datong (northeastern China) are plotted in Fig. 1b, c and d respectively. They can be divided into three types: an island-arc type enriched in K, Ba, Sr and Rb and depleted in Ta or Nb and Ti, a transitional type which shows a much weaker island-arc signature, and a normal type with a NAP typical of ocean island and continental alkali basalts. The island-arc type is confined

Fig. 1 *a*, Normalized abundance pattern (NAP) diagram for a typical ocean island alkali basalt⁶ (○) and tholeiite⁶ (●) from Hawaii, average continental alkali basalt (Δ) from Kenya⁷, average island-arc calc-alkali basalt⁴ (○) and tholeiite⁴ (●) and average depleted mid-ocean ridge basalt⁴ (+). *b*, NAP diagram showing the range of value for six alkali basalts from Rishiri Island, northeastern Japan. The patterns show a strong island-arc signature. *c*, Selected NAPs for transitional alkali basalts from southwestern Japan. The patterns were selected to show the highest K^* value [1.51 (×)], the lowest value [0.84 (□)] and two intermediate values (●). *d*, Variations in the NAPs for normal alkali basalts from Datong, northeastern China and Jejudo Island, Korea. Note all element abundances in *a*–*d* are normalized to their concentration in the primitive mantle.

to northeastern Japan, the transitional type to southwestern Japan and the normal type to Korea and northeastern China.

The geographical distribution of the three types of alkali basalt is summarized in Fig. 2 where the average value of $K^* = 2[K/(Ta + La)]_n$ (abundances of all three elements are normalized to primitive mantle values) is plotted for the alkali volcanic centres studied in this project and for primary magma compositions of sub-alkali volcanic centres studied by Sakuyama and Nesbitt⁸. This ratio was chosen because Ta and La are adjacent to K on the NAP diagram. K^* can be taken as a measure of the amount of K enrichment and therefore the intensity of the island-arc signature. As shown in Fig. 1*a*, ocean island and continental alkali basalts are typically depleted in K relative to La and Ta (that is, $K^* < 1$).

K^* values for primitive of sub-alkali basalts from northeastern Japan are greater than 2.8, with highest values occurring closest

Fig. 2 A map of the Japan Sea area showing distribution of Cenozoic alkali basalts and $K^* = 2[K/(Ta + La)]_n$ values for each centre, with standard deviation for the alkali volcanic centres studied. Additional data from Sakuyama and Nesbitt⁸ for one alkali (●) and several tholeiitic and calc-alkaline volcanic centres (*) in northeastern Japan are also plotted. Note that northeastern Chinese Cenozoic basalts³⁶ have K^* values < 1 (negative K anomalies). Symbols: RI, Rishiri Island; IG, Ichinomegata; OD, Oki-Dogo; CH, Chugoku; NK, northwestern Kyushu; TS, Takashima; JI, Jejudo Island; UI, Ulungdo Island; DA, Datong

to the Japan Trench. The highest K^* value for alkali basalts from northeastern Japan (4.1) is also from the centre closest to the trench, with the value for Rishiri Island, further from the trench in this area, being appreciably less. The average value of K^* for centres from southwestern Japan varies between 1.1 and 1.2, although individual samples may have values as low as 0.84. Samples from Korea and northeastern China invariably have values below 1.0. Figure 2 shows that K^* values for alkali basalts decrease away from the Pacific plate trench. Variations in Ba, Sr and Rb abundances show similar trends to the K^* values. The concentrations of major elements and all other trace elements, including Zr, Y and rare earth elements (REE), are similar for all types of alkali basalts in the area studied.

The observation of decreasing K^* values away from the Pacific plate trench is apparently at odds with Kuno's study⁹ which showed that that K_2O content of Japanese volcanic rocks increase with distance from the trench. We interpret the increase in K_2O to be due to decreasing degrees of partial melting and the change in K^* values to be due to a decrease in subduction-related alteration of the mantle with increasing distance from the trench. Thus the two observations are not incompatible.

The lack of a significant difference in major and trace elements (Th, Zr, Y and REE) for samples from Japan, Korea and northeastern China suggests that the alkali basalts from each of these areas formed by similar processes. If this is correct, the observed enrichments in Ba, K, Sr and Rb must reflect differences in the concentration of these elements in the source. Since the Japanese alkali basalts are found above the subducted Pacific plate except in the northwestern Kyushu area, the obvious explanation for the differences is that the mantle above the subduction zone has been contaminated by K, Ba, Sr and Rb bearing metasomatic solutions and/or partial melts derived from the slab^{10,11}.

Alkali basalts from southwestern Japan show little evidence of an island-arc signature in spite of their proximity to the Philippine Sea plate subduction zone. This is a young subduction zone and the angle of subduction is shallow^{12–14}. We believe that the island-arc type geochemical signature is absent from

Fig. 3 Lead isotope compositions of Japanese alkaline, tholeiitic and calc-alkaline basalts¹⁸⁻²⁰, oceanic sediments^{3,37,38} and MORB^{39,40}. All those analyses carried out by the PbS method were recalculated to 'absolute values' for comparison with those analysed by the silica-gel method using a correction factor of -0.35% per mass unit. The data for Ulungdo Island are unpublished analyses by D. Nelson (personal communication). Pb isotopic compositions of basalts in northeastern and central Japan show a mixing relationship between oceanic sediments and MORB, and become less radiogenic with increasing distance from the Japan Trench. In central Japan, the compositional variation with distance is less regular because of the small difference in the distance between volcanic centres. However, the volcanic centre nearest to the trench, Ohshima Island, has the most radiogenic Pb composition. Pb isotope compositions of alkali basalts from southwestern Japan are similar to basalts from Hawaii. In spite of having similar $^{206}\text{Pb}/^{204}\text{Pb}$ ratios to MORB, their $^{208}\text{Pb}/^{204}\text{Pb}$ ratios are much higher than MORB, suggesting an evolutionary history with a higher Th/U ratio and a more primitive source.

this area because the contaminated mantle above the Philippine Sea plate has not reached sufficient depth to be involved in the production of alkali basalts.

Our conclusion that the alkali basalts of northeastern and southeastern Japan have come from mantle sources which have undergone different degrees of subduction-related alteration is supported by studies of mantle xenoliths. Xenoliths from Ichinomegata, northeastern Japan, have abundant hydrous minerals¹⁵ and contain water-rich fluid inclusions^{16,17}, whereas those from southwestern Japan contain a high-temperature, nearly anhydrous mineral assemblage¹⁵. These observations are consistent with the hypothesis that the mantle source of Japanese alkali basalts is strongly contaminated in the north-east, but only weakly contaminated in the south-east.

Further support for this interpretation is provided by available Pb¹⁸⁻²⁰, Sr^{21,22} and Nd²² isotopic studies. Basalts from northeastern and central Japan have a strong component of Pb from oceanic sediments (Fig. 3) which decreases with distance from the trench, that is, the sedimentary Pb component is the strongest in arc tholeiites and weakest in alkali basalts. In contrast, alkali basalts from southwestern Japan show Pb systematics similar to basalts from nonradiogenic ocean islands such as Hawaiian tholeiites²³. These observations suggest that the fluids (or melts) which contaminated the mantle in northeastern Japan had a strong sedimentary component and that this component decreased in importance with increasing distance from the Pacific plate trench. The implication is that the sedimentary components which contaminate the overlying wedge are con-

Fig. 4 A diagrammatic model of magma generation above the Japanese subduction zone. The subducted slab dehydrates or melts as it descends, releasing a fluid which contaminates the overlying mantle (cross-hatched zone). The intensity of this contamination decreases with increasing distance from the trench. Oceanic sediments (dotted zone) are also carried down by the subducted slab, but dehydrate (or melt) at shallow depths so that their influence is confined to volcanic centres close to the trench. All volcanic rock types from northeastern Japan have come from a strongly contaminated MORB-type source. The alkali basalts of southwestern Japan are believed to originate deeper in the mantle from an OIB-type source and to have interacted chemically with an overlying contaminated MORB-type mantle during their ascent. Alkali basalts from China and Korea were probably produced by a similar process but did not interact with a subduction-contaminated mantle.

sumed at relatively shallow depths. Sr and Nd isotopic studies of basalts from northeastern Japan also require the mantle to be contaminated by a component derived from subducted oceanic sediments^{4,22}.

Figure 4 is a summary diagram which relates our geochemical data and the available isotopic data for Japanese volcanics to existing petrological²⁴⁻²⁹ and convection models³⁰⁻³² for island-arc systems. Pb, Sr and Nd isotopic studies require at least two types of mantle to produce the volcanic rocks of Japan; a mid-ocean ridge (MORB) type and an ocean island (OIB) type. The tholeiitic and alkalic volcanics of northeastern Japan required a MORB-type source which has been strongly contaminated by fluids and/or melts derived from the subducted Pacific plate. The intensity of this contamination decreases with distance from the trench. We suggest that the plumes that give rise to the alkali volcanics of southwestern Japan originate from an OIB-type source at a much greater depth. As the ascending plumes rise, they assimilate some of the overlying contaminated mantle and, in doing so, acquire a weak island-arc geochemical signature. The alkali basalts of northeastern China and Korea show no evidence of an island-arc signature and are geochemically indistinguishable from ocean island alkali basalts. Chemical and isotopic variations observed in these alkali basalts may have resulted from interaction between heterogeneous plume source material and the continental lithosphere.

The absence of a sedimentary Pb component from alkali basalts of southwestern Japan, which show a mild island-arc geochemical signature, is difficult to reconcile with a geochemical model which requires oceanic sediments to be subducted in an island-arc system and recycled through the mantle^{33,34}. Our observations suggest that the sedimentary component is consumed at shallow depths during subduction through repeated dehydration and partial melting as the oceanic lithosphere sinks into the mantle. Sedimentary components may be recycled into the mantle as a consequence of subduction related to continental collision³⁵, recycling of the mantle wedge above the subduction zone or delamination and recycling of the lithospheric mantle³⁵ previously processed through the island-arc environment.

We thank E. Takahashi, H. Takamura, T. Yoshida, M-W. Lee, Y-K. Kim and C-Y. Cui for donating samples from Oki-Dogo,

Chugoku, Rishiri Island, Jejudo Island, Ulungdo Island and Datong respectively. S-s.S. publishes with permission of the Director of Bureau of Mineral Resources Australia. We also thank A. W. Hofmann for his critical comments.

Microzones surrounding phytoplankton form the basis for a stratified marine microbial ecosystem

James G. Mitchell, Akira Okubo & Jed A. Fuhrman

Marine Sciences Research Center, State University of New York, Stony Brook, New York 11794-5000, USA

Although there are 10^7 – 10^9 bacteria per litre of sea water and up to 50% of marine primary productivity passes through them¹, no direct information exists on small-scale spatial distributions of individual bacteria. It has been proposed that bacteria cluster around particulate nutrient sources²⁻⁴, but evidence for this is indirect, based on the presence of chemotaxis in isolates and a broad range— 10^{-9} – 10^{-4} M—of uptake affinity constants⁵. These data have led to the suggestion that there exist oceanic microzones having utilizable dissolved organic carbon (uDOC) orders of magnitude above background concentrations⁶. Here, our calculations of size (10^{-1} cm), utilizable DOC concentrations (10^{-9} – 10^{-7} M) and lifetimes of these nutrient gradients suggest that bacteria cluster around phytoplankton in low-turbulence layers and sheets comprising the thermocline. There, phytoplankton may sink slowly enough for bacteria to keep up with them, and mixing times are long enough to allow nutrient gradients to develop and bacteria to track these gradients. However, very favourable conditions are required for microzone concentrations to be significantly above background.

The size of the nutrient field was calculated from the excretion rate per cell and the dispersion of nutrients away from the cell.

We assumed that 40% of a phytoplankter's primary production is excreted; this represents a generous intermediate value from the wide range cited in the literature^{5,6}. We used high values for phytoplankton productivity⁷ (10^{-4} g C per l per day, over a 12-light period) and cell concentration⁸ (10^6 cells per l) (a more typical value is 10^{-5} g C per l per day). Based on recalculations of Chrost and Faust's⁸ data, we used 100 g as the weight of carbon per mole, and this indicates that 85% of the molecules that phytoplankton excrete have a relative molecular mass <500; amino acids and sugars are the major components of this size fraction⁹. These values result in a total flux out of a cell of 10^{-17} mol s⁻¹.

From the total nutrient flux per cell and the diffusivity of nutrient away from the cell, we determined the dimension of the microzone around a phytoplankter using equation (1)¹⁰

$$\text{Radius} = \frac{(\text{total flux})}{(4\pi)(\text{concentration})(\text{diffusivity})} \quad (1)$$

Here, radius means the distance at which the nutrient gradient emanating from the cell is enhanced 10% above the background concentration. We used a background concentration of 10^{-8} M or 10^{-11} mol cm⁻³ (ref. 11), a relatively low value that again favours microzones (a more typical value, including carbohydrates, is 10^{-7} M; ref. 12). Consequently, 10% of the background level is 10^{-9} M (represented by concentration in equation (1)). Equation (1), using 10^{-5} cm² s⁻¹ for diffusivity¹³, gives a radius of 8×10^{-2} cm or ~1 mm. At this distance from the cell the concentration is theoretically 1.1×10^{-8} M, compared with 1×10^{-8} M for background. For the more typical values cited above, the radius is < 10^{-3} cm.

To determine the significance of the larger microzones, we are interested in the complete range of concentrations. The concentration at the phytoplankter surface represents the maximum enhanced concentration. To estimate this maximum surface concentration, equation (1) was rearranged, and we assumed a relatively small diatom radius of 5×10^{-4} cm to minimize surface area and thus maximize surface concentration (a more typical value is about three times as large). The resulting maximum concentration, under optimum conditions, is $\sim 10^{-7}$ M. For the more typical values cited above, this maximum is $\sim 5 \times 10^{-9}$ M, or barely above background. Thus, if much higher concentrations exist in the literature, diffusion must be restricted by a physical barrier, such as mucus.

One must also compare the formation time of the zone with its rate of disintegration by turbulence. Based on Carslaw and Jaeger¹⁰, we calculate that it takes at least 10^2 s for the leading edge of the excreted material to reach a radius of 1 mm. Table 1 demonstrates that nutrients are dispersed long before reaching a radius of 1 mm, except in low-turbulence conditions such as

Table 1 Lifetimes of Kolmogorov eddies within the range of turbulence found in the ocean

Energy (E) dissipation (cm ² s ⁻³)	Eddy			
	Length (cm)	Velocity (cm s ⁻¹)	Lifetime (s)	Typical location
10^{-2}	0.10	0.10	1.0	Mixed layer
10^{-3}	0.18	0.056	3.2	Mixed layer
10^{-4}	0.32	0.030	10	
10^{-5}	0.56	0.018	32	
10^{-6}	1.0	0.010	100	Thermocline
10^{-7}	3.2	0.0056	320	Thermocline

Kolmogorov eddies are the hydrodynamic 'units' which contain a phytoplankter and its microzone. The necessary equations are from Batchelor²⁷. Values are from Ozmidov²⁸ and from Gregg²⁹. Length = $(v^3/E)^{1/4}$; velocity = $(vE)^{1/4}$; lifetime = $(v/E)^{1/2}$, where v = kinematic viscosity of water (10^{-2} cm² s⁻¹)

the thermocline. The thermocline is composed of 1–5-m-thick 'layers', regions of minimal turbulence separated by 1–10-cm-thick sheets of near-laminar flow¹⁴. Sheets and layers also characterize the 'mixed' layer on calm days¹⁴. We suggest that sheets and layers are the most likely location for microzones for two reasons: (1) in these areas a nutrient gradient has time to reach steady state around a phytoplankter, and (2) bacteria have time to track this gradient chemotactically. The latter point is explained below, but essentially bacteria cannot move by chemotaxis fast enough to form a cluster in less than ~100 s.

For bacteria to cluster around a phytoplankter, they must find, enter and stay within the nutrient gradient. Bacterial sensitivity to chemical gradients^{15,16} and their ability to orient to them is well documented^{17,18}. However, in conventional chemotaxis studies, the nutrient source is stationary and the bacteria are given minutes to hours to orient^{2,19}. Motile bacteria swim, stop, randomly reorient, and swim again. Bacteria approach a nutrient source because runs between stops are longer when they move up a gradient than when they move down one¹⁷. Random reorientation means that bacteria move discontinuously up a gradient in a biased random walk. Consequently, net movement in a gradient is only ~1–3 $\mu\text{m s}^{-1}$, about an order of magnitude slower than their average swimming speed of 10–30 $\mu\text{m s}^{-1}$ (ref. 20). These values derive from laboratory studies of enteric bacteria. The rates for marine bacteria are probably similar, but unknown; if they differ significantly our conclusions are altered accordingly.

It is important to compare the rate of bacterial chemotaxis with the motion of phytoplankton. In the ocean's mixed layer an average non-motile phytoplankter, such as a diatom, sinks at a rate of ~10 $\mu\text{m s}^{-1}$ (1 m per day; ref. 21) or about three times the speed at which a bacterium can move chemotactically towards a nutrient source. This suggests that bacteria have difficulty in keeping up with most diatoms and probably cannot overtake or maintain themselves within the nutrient gradient, making clustering of bacteria to form microzones unlikely in the mixed layer. We chose sinking as an example of cell movement because the average values are well documented²¹. But any movement of the nutrient source (relative to the immediately surrounding water) that is more rapid than the bacterial chemotactic rate (~3 $\mu\text{m s}^{-1}$) prevents clustering. Swimming motility is particularly rapid at tens to hundreds of micrometres per s (ref. 22). This supports our hypothesis that microzones most probably occur in the thermocline, as phytoplankton sinking rates are reduced in this region²³. Also, Woods^{14,24} reports that sheets remain turbid while the surrounding water is clear, suggesting that particles are concentrated in the sheets.

The long eddy lifetimes in reduced turbulence may be important to other small-scale processes, such as formation of micro-scale nutrient patches²⁵. Longer eddy lifetimes may allow chemotactic swarming of motile phytoplankton around a zooplankton or nutrient particle. This potential behavioural response may explain how Lehman and Scavia's²⁵ results were possible despite Jackson's²⁶ calculations predicting otherwise.

In summary, generous estimates biased toward high nutrient concentrations show that: (1) significant organic enrichment extends less than 1 mm from a phytoplankter, and (2) the highest concentration, at the cell surface, is enhanced less than 10 times above background. Estimates from the more typical conditions yield apparently negligible microzones. Furthermore, bacteria cannot keep up with phytoplankton moving faster than the bacterial chemotactic swimming rate. The swimming speeds of motile phytoplankton, and average sinking rates of non-motile forms within the mixed layer, appear to preclude clustering. We suggest that clustering is limited to non-motile forms such as diatoms and seems most likely, and perhaps best studied, in the thermocline. There, hydrodynamic fine structure contributes to reduced phytoplankton sinking rates and provides an environment more amenable to maintenance of ordered, small-scale interactions between microbes than is present in the turbulent mixed layer. This may lead to a stratified microbial community across and within the thermocline.

We thank F. Azam, S. Brownlee, M. Scranton, C. Monaco and V. Gerard for comments on the manuscript; and J. Lumley, M. Legier, M. Silver, C. Decker, G. McManus, T. Bell and J. Hudak for discussion. Female mimicry in garter snakes

Robert T. Mason & David Crews

Institute of Reproductive Biology, Department of Zoology,
University of Texas at Austin, Austin, Texas 78712, USA

In many diverse taxa, males of the same species often exhibit multiple mating strategies¹. One well-documented alternative male reproductive pattern is 'female mimicry', whereby males assume a female-like morphology^{2–8} or mimic female behaviour patterns^{9,10}. In some species males mimic both female morphology and behaviour^{2,7,11,12}. We report here female mimicry in a reptile, the red-sided garter snake (*Thamnophis sirtalis parietalis*). This form of mimicry is unique in that it is expressed as a physiological feminization. Courting male red-sided garter snakes detect a female-specific pheromone and normally avoid courting other males. However, a small proportion of males release a pheromone that attracts other males, as though they were females. In the field, mating aggregations of 5–17 males were observed formed around these individual attractive males, which we have termed 'she-males'. In competitive mating trails, she-males mated with females significantly more often than did normal males, demonstrating not only reproductive competence but also a possible selective advantage to males with this female-like pheromone.

On emergence from the winter den, female red-sided garter snakes are usually courted by 10–20, but sometimes as many as 100 males simultaneously, although only one male mates with the female¹³. Males begin to court females when rapid tongue-flicks by the male deliver pheromone cues from the female's dorsal surface to the male's vomeronasal organ^{14,15}. During the spring of 1983, a census was taken of presumed 'mating balls' at a study site in central Manitoba, Canada. In 33 of the observed 200 (14%) mating balls studied, no female was found; instead a single male was being courted by the other males. These

Fig. 1 Results of a simultaneous choice test. In this test a female and a she-male were placed in an arena with 10 courting males. After 5 min the number of males that courted either stimulus animal was recorded.

courted males (she-males) possessed normal hemipenes, testes and accessory sex structures and their mean snout-vent length and body weight did not differ significantly from those of other males taken at random from the population.

The attractiveness of she-males is not caused by prior physical contact with recently emerged females. Males rubbed against a recently emerged, attractive female were not courted by other males, agreeing with field and laboratory observations in which recently mated males that have been in contact with females for up to 1 h have never been observed to be courted. The attractiveness of the she-males appears to be as permanent as that of sexually mature females¹⁶. All of the she-males tested ($n=33$) elicited courtship from sexually active males when tested at 3, 18 and 40 weeks after capture.

Steroid hormone levels were assayed on blood samples taken in the field from males, females and she-males¹⁷. Analysis of variance revealed that females had significantly higher circulating levels of oestradiol than either males or she-males ($P<0.05$, Student-Newman Keuls) (Table 1). Although testosterone levels in males and females were not significantly different, she-males had significantly higher levels of testosterone than either females or males ($P<0.05$, Student-Newman Keuls). There were no significant differences in circulating levels of dihydrotestosterone. Presumably, the high levels of testosterone in the she-males was a result of either higher secretion or reduced clearance from the circulation.

Table 1 Circulating levels of sex steroid hormone in the two male morphs and the female red-sided garter snake

	(n)	Hormone (ng ml ⁻¹)		
		Testosterone	Oestradiol	Dihydro-testosterone
Male	9	5.720 ± 1.655	0.061 ± 0.012	0.231 ± 0.066
Female	9	0.233 ± 0.082	7.703 ± 3.440	0.093 ± 0.017
She-male	9	19.785 ± 5.703	0.075 ± 0.013	0.142 ± 0.025
F ratio (d.f. 2, 24)		7.68	3.69	2.45
F ≥ 3.40, P > 0.05				

Plasma levels of dihydrotestosterone, oestradiol and testosterone were determined by steroid radioimmunoassay. Values are the mean ± s.e.m.

Table 2 Transfer of the attractiveness pheromone

Trial no.	Female	Male	She-male
1	+	—	+
2	+	—	+
3	+	—	+
4	+	—	+
5	+	—	+

Ten sexually active male red-sided garter snakes were placed in an arena at the den site. Pheromone samples obtained from the skin surface of females, males and she-males were then presented to the test males. A sample was scored as attractive if five or more males courted for 10 s. Ten different males were used in each trial.

The pheromone produced by the she-males is apparently indistinguishable from that produced by females. Samples obtained from the skin surface using the non-polar solvent toluene revealed that the skin of females and she-males, but not of males, elicited courtship behaviour from conspecific males at the den site (Table 2). However, in simultaneous choice tests ($n=12$) in which 10 courting males were able to choose between a female and a she-male, the majority of males preferred the female in every case, although in each trial some males also courted the she-male (Fig. 1). Thus, females may produce more of the pheromone or they may produce a qualitatively different pheromone from that of she-males.

Competitive mating trials were conducted in the field in which groups of five males and five she-males were selected at random and released into an arena (1 m × 1 m) with an unmated, attractive female. In a total of 42 mating trials, 29 resulted in a she-male mating with the female and 13 with a male mating; thus, she-males mated significantly more often than did normal males ($\chi^2=11.85$, $P<0.001$). In field observations, she-males joining an established mating ball caused courting males to ignore the female and begin to court the she-male. A possible advantage to the she-male's attractiveness thus lies in an ability to gain a better position in the mating ball by confusing other males.

Currently, breeding experiments and future field work are being designed to resolve an enigma: why are all males not she-males if she-males do indeed have a reproductive advantage over normal males?

We thank Jim Blank, Jim Bull, Michael Moore, Eric Pianka, Mike Ryan and Joan Whittier for discussion; David Hinkley, Jim Bull and Fred Marsteller for statistical assistance; and Maire Anne Diamond and Yuki Morris for technical assistance. Bill Koonz and Merlin Shoesmith of the Manitoba Department of Natural Resources provided permits and contributed immensely to the collection of both animals and data during the field seasons. This work was supported by NIH grant NICHD 16687 and by a National Institute of Mental Health Research Scientist Development Award to D.C.

Related spotted hyaenas forage together but do not cooperate in rearing young

M. G. L. Mills

National Parks Board, Kruger National Park, Private Bag X402, Skukuza 1350, South Africa

Spotted hyaenas (*Crocuta crocuta*) cooperate little in raising their young¹, in contrast to other social carnivores²⁻¹¹. It has been contended that the average relatedness between adult spotted hyaenas in a clan is so low that there is no kin selection pressure in favour of helping to rear young¹². In the southern Kalahari, however, I found that there is a high degree of relatedness between the members of clans and that kin selection may be implicated in ways other than cooperation in raising young.

Two clans were intensively studied in the Kalahari Gemsbok (South Africa) and adjacent Gemsbok (Botswana) National Parks from January 1979 to April 1984. The animals were individually marked or were recognizable. The degrees of relatedness (r) between the members of the clans were calculated making the following assumptions: (1) Females suckled only their own cubs¹. (2) The degree of relatedness between the original three key adult females of the Kousaunt clan (Fig. 1), were equivalent to the mean of the known degrees of relatedness between 10 female pairs from the Kaspersdraai clan, that is 0.38. (3) The resident adult male in a clan at the time when cubs

were conceived was their father. When there were two adult males present (Kousaunt clan, May 1981 to August 1983; Fig. 1), the behaviour of all but one of the females (Guy) towards the second male (Necklace) suggested that they would not have allowed him to mate with them. Accordingly, the male Hans was assumed to have fathered all cubs born during this period, except for Guy's cub, which was not included.

Spotted hyaenas of the southern Kalahari live in clans of 5–20 individuals inhabiting territories of 600–1,900 km² (M.G.L.M., manuscript in preparation). All males ($n=13$) left their natal territories at 2½ to 3½ years old, but only 1 of 8 females did so. The average degree of relatedness between 231 pairs of hyaenas of the Kousaunt clan, which averaged 17 individuals during the study, was 0.29 and between 32 pairs of the Kaspersdraai clan, which averaged eight individuals, was 0.33.

The hyaenas' food consists primarily of large and medium-sized ungulates, 55.3% ($n=197$) of which they killed. Observations of spotted hyaenas hunting gemsbok (*Oryx gazella*) calves (43% of kills), sub-adults and adults (10% of kills) and blue wildebeest (*Connochaetes taurinus*) of all ages (15% of kills), revealed no correlation between hunting success and hunting group size (Fig. 2). Single hyaenas, however, were unable to kill large gemsbok, two and four being the smallest groups observed to catch sub-adults and adults, respectively. It was usually impossible to differentiate between hunting attempts on wildebeest calves and adults, but group size did not appear to be a large factor in determining hunting success, as Kruuk¹ also concluded. Furthermore, carrion, which is usually located by scent, can be located as efficiently by a single hyaena as by

Fig. 1 Summary of the reproductive history of the Kousaunt clan from 1978 to 1983, showing the three coalitions and the subsequent fission of the clan. The birth of a litter is represented by a vertical line descending from the female's line, immigration of an individual is indicated by an oblique line. The ending of a horizontal line by one short vertical line denotes either death or emigration. The names of animals mentioned in the text are given.

Fig. 2 The relationship between spotted hyaena hunting group size and hunting success of a, gemsbok calves, b, gemsbok sub-adults and adults; and c, wildebeest of all ages.

several. Of 566 foraging groups, 29.9% comprised one, 19.3% two, 18.7% three, 13.3% four, and 19.2% five or more animals. Foraging groups sizes, therefore, were often larger than needed for maximum foraging efficiency, so cooperation in hunting may not be the only selective pressure for group foraging in these spotted hyaenas.

Another reason for group foraging could be that larger groups are more successful at defending their food from competitors^{13,14}. In the southern Kalahari, however, spotted hyaenas and their chief competitors, lions (*Panthera leo*), are few. Only once did I observe other hyaenas (and on three occasions, lions) trying to appropriate a carcass from feeding spotted hyaenas ($n = 197$).

Could spotted hyaenas form these larger foraging groups to allow closely related individuals access to food, thus possibly enhancing their inclusive fitness? The degrees of relatedness between the members of 131 foraging groups of Kousaunt hyaenas and 28 foraging groups of Kaspersdraai animals, were compared with those for equal numbers of equal-sized foraging groups randomly generated by a computer from the pool of available hyaenas in each clan. In both cases the degrees of relatedness in the foraging groups were significantly higher than they were in the random groups (Kolmogorov-Smirnov one-sample test: Kousaunt, $D = 0.227$, $P < 0.01$, two-tailed test; Kaspersdraai, $D = 0.149$, $P < 0.01$, two-tailed test). These hyaenas, therefore, showed a strong tendency to preferentially forage with their close kin.

Certain individuals were often excluded from food. I compared the degrees of relatedness of only those members of 32 feeding groups from the Kousaunt clan that were permitted to eat at a given carcass, with those of 32 random groups from the clan, chosen as described above. Here again the degrees of relatedness were significantly higher in the observed groups than in the random groups (Kolmogorov-Smirnov one-sample test, $D = 0.088$; $P < 0.01$, two-tailed test).

In 1983 a split occurred in the expanding Kousaunt clan (Fig. 1). Three coalitions comprising the three surviving original adult females plus their offspring (Fig. 1) developed in the clan (unpublished observations); this reached a climax in August 1983 when all the members of the Olivia and Two-Two coalitions were observed to engage in a fierce intra-clan fight. The battle probably was not their first as, prior to this, two members of the Olivia coalition had sustained injuries. After the battle the Two-Two coalition, together with the male (Necklace) (Fig. 1) departed and settled in an adjoining area. The Olivia and Ella coalitions continued to inhabit the same area and den communally.

Relatedness between individuals, therefore, is more important in spotted hyaena society than was thought previously. Apart from sharing dens, why then do they not cooperate in raising young as brown hyaenas (*Hyaena brunnea*) do^{10,11}? Regurgitation of food for young is not seen in the Hyaenidae, probably because of the rapid rate at which food passes from the stomach to the intestines¹. Food carrying, which is observed in the brown hyaena, would be difficult to accomplish in spotted hyaenas¹⁵ as: (1) much of their food consists of large carcasses, which the hyaenas often have to travel long distances to obtain; (2) the social nature of their feeding habits¹ means that there is often nothing suitable left to take back to a den; and (3) at the communal dens the larger cubs would get most of the food. Cubs, therefore, rely heavily on their mother's milk during their first year¹; this imparts a heavy nutritional load on the females, which may only be able to afford to suckle their own offspring. Finally, the small den tunnels^{1,16,17} provide ideal protection for cubs when the adults are away, thus precluding the need to leave guards. I suggest that spotted hyaenas cooperate little in raising their young because of ecological pressures and not because of low levels of relatedness between clan members.

I thank the National Parks Board for logistic support, Michael Knight and Hermanus Jaegers for help in the field, Peter Retief for help with statistics and Drs David Macdonald and Anthony Hall-Martin for comments.

Defective ability to self-renew *in vitro* of highly purified primitive haematopoietic cells

Elaine Spooncer, B. I. Lord & T. M. Dexter

Paterson Laboratories, Christie Hospital and Holt Radium Institute, Withington, Manchester M20 9BX, UK

Stromal cells play a critical role in haematopoiesis, both in a permissive and, probably, in a directive manner¹⁻⁵. Study of the interactions between stromal cells and haematopoietic stem cells, however, is difficult to perform using whole bone marrow, in which stem cells are indistinguishable from precursor cells and maturing haematopoietic cells, and where stromal and haematopoietic cells co-exist in a heterogeneous mixture. We have purified primitive haematopoietic spleen colony-forming cells (CFU-S) using fluorescence-activated cell sorting (FACS) and produced CFU-S populations which approach 100% purity (ref. 6 and B.I.L. and E.S., in preparation). This cell population is devoid of significant stromal cells and mature haematopoietic cells. Here, we report that when purified CFU-S are seeded onto a stromal adherent layer *in vitro*, foci of haematopoietic cells develop within the stroma followed by production of a wave of maturing and mature progeny. However, self-renewal of CFU-S does not occur and haematopoietic activity rapidly declines, indicating that caution should be applied in the use of highly purified stem cells for human bone marrow transplantation.

Irradiated long-term marrow culture adherent layers were used as the source of inductive haematopoietic stroma². We seeded the stroma (or empty culture flasks) with various numbers of normal marrow cells (Table 1). Normal bone marrow cells (5×10^5 containing 130 CFU-S) plated into an empty tissue-culture flask produced two small stromal cell foci per flask and no haematopoietic cells over 7 weeks. The same number of normal bone marrow cells plated onto an irradiated adherent layer led to the production and release of CFU-S into the growth medium for several weeks. Note that this is an underestimate of the total CFU-S as this does not include the CFU-S lodged in the adherent cell layer⁷. It is not known why haematopoiesis was exhausted in these cultures after 7 weeks. A larger inoculum of normal bone marrow cells, 5×10^6 cells, used to initiate a long-term bone marrow culture adherent layer, produced a confluent stromal adherent layer that promoted the maintenance of relatively few CFU-S for a limited duration, as described previously⁸. However, when 5×10^6 normal bone marrow cells were seeded onto an irradiated adherent layer, many CFU-S were produced for several weeks and the duration of haematopoiesis was clearly extended. In agreement with previous studies, fully competent long-term bone marrow cultures could be established from 1.5×10^7 normal bone marrow cells

Table 1 CFU-S production in irradiated marrow stromal cell layers and control flasks inoculated with normal marrow cells

Input normal bone marrow	Input CFU-S	Irradiated stromal cells	CFU-S per culture (release to growth medium) (weeks)						
			1	2	3	4	5	6	7
5×10^5	130	No	0	0	0	0	0	0	0
5×10^6	1,300	No	91	20	30	20	10	0	13
1.5×10^7	13,000	No	700	386	432	576	580	624	394
0	0	Yes	0	0	0	0	0	0	0
5×10^5	130	Yes	18	39	101	40	92	16	0
5×10^6	1,300	Yes	139	250	650	250	130	ND	100

To establish irradiated marrow stromal cell layers, we set up long-term bone marrow cultures as described previously¹. Briefly, each culture was initiated by flushing the contents of one femur (1.5×10^7 cells) from (C57BL/6 $\times$ DBA/2) F₁ donors into 10 ml Fischer's medium (Gibco) supplemented with horse serum (20% v/v) (Flow Labs) and 10^{-6} M hydrocortisone sodium succinate. Cultures were fed weekly by removing 5 ml growth medium and adding 5 ml fresh medium. After 4 weeks the cultures were irradiated with 1,500 rad ¹³⁷Cs, followed by a total change of medium 6 h later. The dose kills all haematopoietic cells yet spares relatively quiescent stromal cells and provides a nude inductive stroma that can function to promote the growth of haematopoietic cells for at least several weeks². The stromal cell layers were gently rinsed with Fischer's medium 7–10 days after irradiation and the appropriate number of fresh bone marrow cells was added in 10 ml Fischer's medium with 20% v/v horse serum. At weekly intervals, cultures were fed and the suspension cells collected during feeding were diluted (if necessary) and assayed for CFU-S according to the method of Till and McCulloch¹². Recipient mice were killed after 10 days. In some experiments, fresh bone marrow cells were seeded into empty culture flasks. ND, not done.

Table 2 CFU-S production in irradiated marrow stromal cell layers inoculated with FACS-sorted bone marrow cells

625	44	Yes	9	2	4
312	22	Yes	—	—	4
20	1.3	Yes	—	—	0
500	26	No	0	0	—

Irradiated long-term bone marrow cultures were established as described in Table 1 legend. Normal bone marrow cells were enriched for CFU-S content by a modification (B.I.L. and E.S., in preparation) of the electronic sorting technique described by Visser *et al.*⁶ Normal bone marrow cells were labelled with $2 \mu\text{g ml}^{-1}$ fluorescein isothiocyanate-conjugated wheat-germ agglutinin (WGA-FITC) and subjected to a density cut in metrizamide. Cells with density $\leq 1.080 \text{ g ml}^{-1}$ were collected, washed in phosphate-buffered saline and 'sorted' on a fluorescence-activated cell sorter (FACS IV; Beckton & Dickinson). Electronic windows were set to select highly WGA-FITC-labelled cells with moderate forward and low perpendicular light scatter. The selected cells were collected in Fischer's medium containing 10% horse serum, washed and re-sorted under the same criteria as before. WGA-FITC was removed from the re-sorted cells by incubating for 15 min at 37 °C in isotonic, 0.2 M *N*-acetyl D-glucosamine⁶ before assaying the processed cells for CFU-S content¹². Recipient mice in the CFU-S assay were killed after 12 days. The FACS-BM contained 70–90 CFU-S per 10^3 cells. In accordance with the measured seeding efficiency of the FACS-BM cells to the spleen (data not shown), the concentration of FCS-S was calculated to be 50–107%. The appropriate number of FCS-BM cells were seeded onto the irradiated stromal cell layers, cultures terminated at various times and the adherent cells scraped off the flask and pooled with the suspension cells. One-fifth of each culture was injected into five irradiated mice to measure total CFU-S per culture. The results of one experiment are shown here, but we have obtained identical results in four other experiments.

with subsequent production of high numbers of CFU-S for many weeks¹. From these data we can conclude that an inoculum of normal bone marrow containing ~ 130 CFU-S is capable of colonizing a haematopoietic environment and maintaining self-renewal for at least 4–5 weeks. There does not seem to be appreciable stromal cell contribution to the irradiated stromal elements by the fresh normal bone marrow cells at this dose.

When various numbers of FACS-treated bone-marrow cells (FACS-BM cells) were seeded onto irradiated adherent layers and the cultures were terminated after 1,2 or 3 weeks to measure

Table 3 Generation of putative haematopoietic cell foci in irradiated marrow stromal cell layers

Input FACS-BM	Foci of putative haematopoietic cells (weeks)

Foci present in 60–100% random fields of view (++); 30–60% (+), 1–30% (+/-), no field of view (—). Irradiated marrow stromal cell layers were seeded with FACS-BM exactly as described in Table 2 legend. Cultures were examined weekly using a Leitz diavert inverted microscope. Foci of putative haematopoietic cells were classified according to the scheme above.

Table 4 CFU-S production in irradiated marrow stromal cell layers inoculated with reconstituted FACS-BM cells

Input	Input CFU-S	CFU-S per total culture (weeks)			
		1	2	3	4
NBM 5×10^5	130	34	240	174	132
Reconstituted FACS-BM 6.5×10^5	180	>250	>250	ND	185

Irradiated marrow stromal cell layers were established, seeded with cells and assayed weekly for total CFU-S per culture as described in Tables 1 and 2 legends. In one set of cultures, 5×10^5 normal bone marrow cells were seeded onto irradiated marrow stromal cell layers. For another set, the bone marrow was sorted through the FACS as described in Table 2 legend. After sorting, the FACS-BM was recombined with cells rejected at the metrizamide stage and during the FACS sorting to produce reconstituted FACS-BM cells, which were seeded onto irradiated marrow stromal cell layers.

the total CFU-S present in the growth medium and within the adherent layer, we consistently detected few or no CFU-S (Table 2). Apparently the FACS-BM CFU-S are neither maintained nor produced in such cultures, even when an inoculum of 700 CFU-S was used, equivalent to $\sim 3 \times 10^6$ normal bone marrow cells. Although these cultures were devoid of CFU-S, survival and production of maturing haematopoietic cells occurred. When the FACS-BM cells were plated onto the stromal cells, clonal foci of haematopoietic cells developed in the adherent layer. The number of foci was roughly proportional to the

number of FACS-BM cells introduced to the cultures and their sequential development from two or four cell foci into typical 'cobblestone' areas composed of hundreds of cells was observed. Furthermore, these foci were not stable and we observed the appearance, growth and disappearance of individual foci over a period of days (Table 3). Later than this, no foci were seen and the adherent layer became infiltrated randomly by macrophage-type cells. The cells in these foci are clearly not CFU-S; granulocyte-macrophage colony-forming cell assays (data not shown) only detected many macrophage cluster-forming cells. However, at the time of peak cobblestone formation the cell counts in the growth medium were often $>10^5$ per ml and the cells being produced consisted of blast cells, immature and maturing neutrophils and macrophages. Because of this, it is likely that the foci consist of maturing myeloid cells, although the identity of the blast cells is unknown.

From these data it is clear that normal bone marrow cells (containing limited numbers of CFU-S) can maintain haematopoiesis for some weeks, whereas FACS-BM (containing the same number of, or more, CFU-S) shows no ability to self-renew CFU-S or to establish long-term haematopoiesis *in vitro*. However, the FACS-BM cells can 'colonize' the stroma and form foci of cells of haematopoietic origin that undergo a limited amount of proliferation and development. The inability of FACS-BM cells to express self-renewal capacity does not result from the physical and mechanical stress of FACS sorting and the binding and removal of wheat-germ agglutinin as shown in Table 4.

Thus, other possibilities must be considered for the lack of growth of FACS-sorted CFU-S in irradiated long-term bone marrow cultures: (1) Irradiated stroma is defective in its ability to promote self-renewal of CFU-S. This seems unlikely because haematopoiesis can be established on the irradiated stroma by 5×10^5 normal bone marrow cells (which contain few stromal cells). (2) Removal of some accessory cell(s) important for the maintenance or control of CFU-S self-renewal. We are currently investigating this possibility. (3) Lack of feedback inhibition on differentiation. As FACS-BM cells differ from normal marrow cells in the absence of mature cells, it is possible that the mature cells somehow regulate the probability of self-renewal of CFU-S. (4) Finally, it is possible that the CFU-S are not the cells which repopulate haematopoiesis in long-term bone marrow cultures, that is, they are not the most primitive stem cells. Although FACS-purified CFU-S can promote 30-day survival of irradiated mice, no study has been made of the longer-term quality of the CFU-S⁶. The haematopoietic stem-cell compartment is clearly a heterogeneous population^{2,9} and certain elements of the CFU-S population (or even primitive stem cells that do not have spleen colony-forming capacity) may be discarded by the sorting procedure. Thus, although FACS-sorting seems to select for CFU-S with an average (or high) 'self-renewal' capacity *in vivo* in the short term⁶, the CFU-S may still not be representative of the stem cells.

These findings have obvious clinical importance. Recently, various methods for cleaning up human bone marrow cells before transplantation have been described, aimed at removing from the graft T cells^{10,11} responsible for provoking graft-versus-host disease. Treatment of bone marrow grafts in this way usually leads to alleviation of the disease, but also leads to a surprisingly high level of graft failure in some patients, for unknown reasons¹¹. Therefore, an understanding of why FACS-BM CFU-S do not self-renew *in vitro* may explain some of the problems associated with engraftment of human marrow *in vivo*. Our results indicate caution in the use of highly purified human haematopoietic progenitor cells for transplantation. Furthermore, the observation that CFU-S from FACS-BM do not self-renew *in vitro* provides an opportunity to investigate circumstances and conditions required for the self-renewal of haematopoietic stem cells.

Expression of the *c-fms* proto-oncogene during human monocytic differentiation

Eric Sariban, Thomas Mitchell & Donald Kufe

Laboratory of Clinical Pharmacology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts 02115, USA

The McDonough strain of the feline sarcoma virus contains a transforming gene (*v-fms*) which contains partial nucleotide homology with proto-oncogenes encoding tyrosine kinases¹⁻⁴. One of the *v-fms*-encoded products, gp140^{fms}, is a cell surface transmembrane glycoprotein that may function as a growth factor receptor^{5,6}. Although *c-fms* transcripts have been detected in placental trophoblasts⁷⁻¹⁰ and normal human bone marrow¹¹, the role of the *c-fms* gene product is unknown. We now report that induction of monocytic, but not granulocytic, differentiation of human HL-60 leukaemic cells is associated with expression of *c-fms*, preceded by that of *c-myc* and *c-fos*. Because *c-fms* transcripts are also detectable in peripheral blood monocytes and in blasts from certain patients with myelomonocytic leukaemia, the *c-fms* gene product may play a role in monocytic differentiation.

The *c-fms* gene and the normal cellular homologue of the transforming gene of the FBJ murine osteosarcoma virus (*v-fos*) are transcriptionally active in the cells of mouse extra-embryonal membranes⁷⁻¹⁰. Expression of the *c-fms* gene was undetectable in a variety of postnatal mouse tissues⁷⁻⁹, whereas *c-fos* transcription was restricted to haematopoietic cells¹⁰. This specific pattern of transcriptional activity suggests that both *c-fos* and *c-fms* are involved in certain differentiation pathways^{7,9}. *c-fos* gene expression is associated with monocytic differentiation^{10,12,13} and *c-fms* transcripts have been detected in undifferentiated mouse haematopoietic cells¹², certain human tumours¹⁴ and normal human bone marrow¹¹. Moreover, the detection of *c-fms* sequences on chromosome 5 (ref. 15) and an association of the 5q⁻ syndrome with certain myelodysplastic syndromes¹⁶ and acute myelogenous leukaemia¹⁷ suggested that *c-fms* gene expression is related to haematopoietic cell differentiation.

We have used the human HL-60 promyelocytic cell line¹⁸ to study the role of *c-fms* expression during induction of haematopoietic cell differentiation. HL-60 cells mature morphologically and functionally towards granulocytes after induction with dimethyl sulfoxide (DMSO) or hexamethylene bisacetamide (HMBA)^{19,20}. In contrast, these cells can be induced to differentiate along a monocyte-macrophage pathway when treated with 12-*O*-tetradecanoylphorbol-13-acetate (TPA)²¹ and 1,25 dihydroxy-vitamin D₃ (1,25(OH)₂D₃)²². HL-60 cells were collected 24 and 72 h after addition of each of these inducers to monitor for *c-fms* expression. Although no *c-fms* RNA was detected in uninduced HL-60 cells (Fig. 1, lane 1), *v-fms* DNA hybridized with a 5-kilobase (kb) transcript detectable after 24 h of TPA and 1,25(OH)₂D₃ treatment. In contrast, *c-fms* RNA was not detected following induction of HL-60 cells with DMSO and HMBA. Similar results were obtained after

Fig. 1 Level of *c-fms* RNA during induction of HL-60 monocytic (TPA and 1,25(OH)₂D₃) and granulocytic (DMSO and HMBA) differentiation. HL-60 cells were grown as described previously¹⁸ in the presence of 3.3×10^{-8} M TPA (Sigma), 5×10^{-7} M 1,25(OH)₂D₃ (Hoffman-LaRoche), 1.25% DMSO or 4 mM HMBA for 24 h. Total cellular RNA was purified by the guanidine thiocyanate-caesium chloride method²⁹, analysed by electrophoresis of 15 µg RNA through 1% agarose-formaldehyde gels followed by Northern blot transfer to nitrocellulose³⁰. The 1.0-kb *Pst*I fragment of the *v-fms* gene was purified from the pSM3 plasmid⁴ by preparative gel electrophoresis and nick-translated to specific radioactivities of $\sim 5 \times 10^8$ c.p.m. µg⁻¹ DNA. The filters were pre-hybridized at 42 °C for 16–24 h in buffer consisting of 50% formamide, 5 × SSC, 0.1% SDS, 5 × Denhardt's and 200 µg ml⁻¹ salmon-sperm DNA. The RNA blots were then hybridized for 16–24 h at 42 °C with 2×10^6 c.p.m. nick-translated probe per ml hybridization buffer (same as the pre-hybridization buffer, with 1 × Denhardt's). After hybridization, the blots were washed twice in 2 × SSC, 0.1% SDS at room temperature for 60 min and then washed twice in 0.1 × SSC, 0.1% SDS at 55 °C for 30 min. The blots were then dried and exposed to X-ray film with an intensifying screen at -70 °C. Cytocentrifuge smears of HL-60 cells were examined after 3 days of continuous drug exposure for α-naphthyl acetate esterase (NSE) activity and nitroblue tetrazolium (NBT) reduction³¹. Adherence to the tissue culture flask was also monitored on day 3. Control HL-60 cells: 0% adherence, 13.3 ± 1.5% NSE positive, 7.3 ± 1.5% NBT positive; TPA-treated cells: 84.7 ± 1.8% adherence, 71.3 ± 2.9% NSE, 13.3 ± 2.4% NBT; 1,25(OH)₂D₃-treated cells: 0% adherence, 86.0 ± 5.6% NSE, 99.3 ± 0.8% NBT; DMSO-treated cells: 0% adherence, 19.3 ± 3.3% NSE, 94.3 ± 1.9% NBT; HMBA-treated cells: 0% adherence, 0% NSE, 84.5 ± 3.4% NBT. (Results are expressed as mean ± s.d. of four determinations).

72 h treatment with each inducer and *c-fms* transcripts were not detected (data not shown) after TPA exposure of an HL-60 blast subclone²³ that does not undergo differentiation following treatment with inducers of monocyte or granulocyte differentiation. Taken together, these findings suggest that *c-fms* is induced when the HL-60 cells mature along the monocyte-macrophage pathway and that TPA is not a general inducer of *c-fms* gene transcription.

The temporal relationship between the addition of TPA and *c-fms* expression is shown in Fig. 2a. The *c-fms* transcripts appear 6 h after TPA addition, whereas maximum levels of *c-fms* RNA were present following 24–48 h of induction. These findings contrast with *c-myc* expression which, as shown previously²⁴, was not detected 24 h after TPA induction (Fig. 2a). Similar declines in *c-myc* transcripts occur following TPA treatment of HL-60 cells¹⁹, but these changes in *c-fms* and *c-myc* RNA during induction of HL-60 monocytic differentiation were not associated with altered *N-ras* or actin gene expression (Fig. 2a). We have also monitored *c-fms* expression during 5 days of TPA or 1,25(OH)₂D₃ treatment and find that *c-fms* RNA remains detectable following induction with 1,25(OH)₂D₃ (Fig. 2b). Similar results have been obtained after induction with TPA. Moreover, TPA treatment of HL-60 cells for 20 min is sufficient for commitment along the monocyte differentiation pathway¹³. The *c-fms* transcripts, however, were not detectable 24 h after a similar 20-min TPA exposure (data not shown).

Within 1 h of treating HL-60 cells with TPA, *c-fos* messenger RNA is detectable¹³. We have also examined the relationship

Fig. 2 Temporal relationship of *c-fms* expression during induction of HL-60 cells by TPA and 1,25(OH)₂D₃. **a**, HL-60 cells were treated with 3.3×10^{-8} M TPA for 6, 24 and 48 h. RNA (15 µg) was then hybridized to the ³²P-labelled nick-translated cDNA probes. The 1.6-kb *Cl*AI/*E*coRI fragment of the human *c-myc* 3' exon was purified from the pMC41-3 RC plasmid³². The 1.5-kb *p*52C-*E*coRI fragment of the HL-60 *N-ras* gene was purified from a reconstructed pBR322 plasmid³³. The 2.0-kb *Pst*I fragment of the chicken β-actin gene was purified from the pA1 plasmid³⁴. All methods are described in Fig. 1 legend. **b**, HL-60 cells were treated with 5×10^{-7} M 1,25(OH)₂D₃ for 24, 72 and 120 h. RNA (20 µg) was then hybridized to the ³²P-labelled *v-fms* probe.

Fig. 3 **a**, Relationship between expression of *c-fms*, *c-fos* and *c-myc* in TPA-induced HL-60 cells; **b**, effect of protein synthesis inhibition on *c-fms*, *c-fos* and *c-myc* expression. **a**, HL-60 cells were treated with 3.3×10^{-8} M TPA and collected at the times indicated. Total cellular RNA (20 µg) and specific transcripts were detected by hybridization to ³²P-labelled complementary DNA probes as described in Figs 1, 2 legends. The 1-kb *Pst*I fragment of the *v-fos* gene was purified from the pfos-1 plasmid³⁵. **b**, HL-60 cells were treated for 6 or 24 h with 3.3×10^{-8} M TPA alone and in combination with cycloheximide (+CH). Procedures for RNA preparation and analysis were as described in Figs 1, 2 legends except that 20 µg total RNA were used in each lane.

Fig. 4 *c-fms* gene transcripts in human monocytes and blasts from patients with myelomonocytic leukaemia. Peripheral blood monocytes and blasts from patients with myelomonocytic leukaemia were prepared as described previously²⁹. The ³²P-labelled *v-fms* probe was then hybridized to RNA (20 µg) obtained from these cell preparations: lane 1, normal peripheral blood monocytes (100% adherent cells); lane 2, TPA-induced HL-60 cells (24 h); lanes 3–6, blast preparations from four patients with myelomonocytic leukaemia (leukaemic blast composition by morphology: lane 3, 80%; lane 4, 79%; lane 5, 73%; and lane 6, 85%). All methods as described in Fig. 1 legend.

between changes in *c-myc*, *c-fos* and *c-fms* RNA during 24 h of TPA induction. The *c-myc* RNA level increased fourfold by 90 min after TPA addition (determined by optical densitometry of the autoradiograph) and then declined to nearly undetectable levels by 6 h (Fig. 3a). As reported previously¹³, *c-fos* transcripts accumulated within 20–30 min following induction, reached a maximum level at 90 min and declined thereafter. In contrast, *c-fms* expression occurred later, 6 h after TPA induction, and increased by 24 h (Fig. 3a). Clearly, the decrease in *c-myc* RNA and the increase of *c-fos* RNA both precede induction of *c-fms* expression.

We have extended our comparison of *c-myc*, *c-fos* and *c-fms* expression by monitoring the effects of cycloheximide on the level of these transcripts. Although *c-fms* expression was detectable in the 6-h TPA-treated cells, concurrent cycloheximide treatment inhibited the induction of *c-fms* RNA. Similar results were obtained after 24 h of TPA and cycloheximide treatment (Fig. 3b). In contrast, cycloheximide increased expression of both *c-myc* and *c-fos* (Fig. 3b). Thus, cycloheximide potentiates expression of the *c-myc* and *c-fos* genes known to be induced by mitogens^{13,25}, whereas our results suggest that induction of *c-fms* RNA requires new protein synthesis.

The differential sensitivity of *c-fos* and *c-fms* expression to cycloheximide, as well as the possible sequencing of these genes, may be related to specific functions of the gene products during monocyte proliferation and differentiation. Transcription of the *c-fos* gene, but not the *c-fms* gene, occurs within minutes of stimulating quiescent mouse fibroblast 3T3 cells with TPA²⁶. The early increase in both *c-myc* and *c-fos* mRNA, but not *c-fms* mRNA, has also been reported in TPA-treated quiescent fibroblasts and suggests that the *c-myc* and *c-fos* gene products are necessary for the mitogenic response²⁶. Conversely, transfection of F9 teratocarcinoma cells with an exogenous *c-fos* gene induces expression of only certain genes in the differentiation programme, thus indicating that maturation to a terminal stage of differentiation requires the expression of additional genes not regulated by *c-fos*²⁷. Thus, in TPA-treated HL-60 cells, the *c-fos*-encoded nuclear protein may play a dual role in both cell growth and initiation of differentiation. In contrast, the *c-fms* gene product may function in terminal differentiation along the monocyte-macrophage pathway.

Therefore, we have monitored the level of *c-fms* transcripts in circulating human monocytes and in blasts from four patients with myelomonocytic leukaemia (Fig. 4), and found that peripheral blood monocytes (Fig. 4, lane 1) and one of four leukaemic blast preparations had detectable levels of *c-fms* RNA (Fig. 4, lanes 3–6). The size of the transcript detected in leukaemic cells was identical to that observed in TPA-induced HL-60 cells (Fig. 4, lane 2) and in circulating monocytes. Furthermore, the 5-kb transcript was also detectable after TPA-induction of the human U-937 cell line to macrophages (data not shown). In contrast, *c-fms* RNA was undetectable in human granulocytes²⁸, peripheral blood T-cells, K562 erythroleukaemia

cells, B-cell lines (Daudi and JY), a T-cell line (MOLT-4) and AG1522 diploid fibroblasts.

Murine myeloid monocytic leukaemia WEHI-3B cells contain two *c-fms* transcripts of 4.1 and 8.4 kb (ref. 9). A smaller 3.7-kb *c-fms* transcript has been detected in mouse placental tissue⁸ and a transcript of the same size has been detected in a trophoblastic cell line (BeWo) derived from a gestational choriocarcinoma of the human fetal placenta⁹. In contrast, the results of the present study suggest that the *c-fms* transcript is 5 kb long in HL-60 and U-937 cells induced along a monocyte lineage, monocytes and certain leukaemic blasts. These differences in transcript size may be related to the physiological function of the *c-fms* encoded products in gestational and haematopoietic tissues.

Thus, expression of the *c-fms* gene has been observed in haematopoietic cell lines induced along the monocyte differentiation pathway. Furthermore, the detection of the *c-fms* transcripts in circulating monocytes, but not granulocytes or lymphocytes, implies that the gene product is involved specifically in the process of monocyte-macrophage differentiation. The localization of *c-fms* to chromosome 5 (ref. 15) is of interest in view of a specific deletion involving this region in refractory anaemia¹⁶ and acute myelogenous leukaemia¹⁷. Unregulated transcription of the *c-fos* gene might lead to uncontrolled proliferation²⁶. In view of the possible sequencing of proto-oncogene expression during monocytic differentiation, it would be of interest to determine whether the *c-fms* gene product regulates the expression of *c-myc* or *c-fos* genes. Thus, a decrease in the production of the *c-fms* gene product could lead to defects not only in the control of cell differentiation along the monocyte lineage, but also in cell proliferation.

We thank Drs T. Curran, B. Patterson, J. Cunningham and F. Wong-Staal for providing the *v-fos*, β -actin, *N-ras* and *c-myc* probes, respectively; and Dr J. Griffin for preparation of human monocytes and leukaemic cells. We also thank Ms Eileen Mongeau for secretarial assistance. This work was supported by PHS grant CA34183 from the National Cancer Institute and by an American Cancer Society Faculty Research Award (D.W.K.).

The class II major histocompatibility antigens, I-A and I-E, have been detected on the surface of certain immunocompetent cells, including B lymphocytes and monocytes¹⁻³. These molecules are involved in cell-cell interactions in the immune responses^{4,5}. Each class II antigen consists of two subunits, α and β chains, and the genes encoding these subunits have been well characterized at the molecular level⁶⁻⁹. To analyse the regulatory mechanism of E_α gene expression and the role of the I-E antigen in the regulation of the immune responses, we have produced transgenic mice by microinjecting cloned E_α^d genes into fertilized eggs of C57BL/6 mice of *b* haplotype. This strain of mouse carries a deletion in the upstream (5') region of the E_α gene covering the transcriptional promoter and, therefore, does not express this gene¹⁰. Interestingly, this genetic defect of the E_α gene is accompanied by the inability of the host mouse to respond to a certain set of antigens, phenomena generally termed *Ir* gene control^{11,12}. We report here that the E_α^d genes are expressed in these transgenic mice to form the I-E $^\alpha E_\beta$ antigen on the surface of B lymphocytes and monocytes and that these I-E antigens are functional in terms of the induction of a mixed lymphocyte reaction and the restoration of immune responsiveness to poly(L-glutamic acid-L-lysine-L-phenylalanine) (GL-Phe).

‡ Present address: Dana Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts 02115, USA.

Fig. 1 Southern blot analysis of the E_α gene in transgenic mice³². DNAs (5 μ g) from liver of BALB/c, C57BL/6 or transgenic mice were digested with *Bam*HI or *Pvu*II, electrophoresed on a 0.5% agarose gel, transferred to a nitrocellulose filter and hybridized with the ³²P-labelled 2.6-kb *Sal*I fragment which includes the first exon of the E_α gene. The host C57BL/6 mice carry a deletion in this region³². Mice 2, 17, 18 and 26 were born from ova injected with E_α^d DNA. Mouse 17 did not contain injected genes. The offspring (nos 2-7 and 2-10) of mouse 2 were produced by mating mouse 2 with a female C57BL/6 mouse. DNAs from mice 2-7 and 2-10 were also analysed by *Bam*HI digestion. Sizes of DNA fragments are in kilobases.

Approximately 200 copies of the 14-kilobase (kb) *Sac*II/*Xho*I fragment containing the entire E_α^d gene sequence were microinjected into each fertilized egg of the C57BL/6 mouse. In total, 30 mice were born. These mice were partially hepatectomized and the DNA isolated from the livers was analysed by Southern blotting to determine whether the injected E_α^d gene is retained in the host DNA. Because of the aforementioned deletion, BALB/c DNA yielded a DNA fragment 0.5 kb larger than that of C57BL/6 DNA when these DNAs were digested either with *Bam*HI or *Pvu*II and the digests analysed with a probe covering the 5' end of the E_α gene (see Fig. 1). This allows us to distinguish the injected E_α^d gene from the endogenous defective E_α^b gene present in the host C57BL/6 mouse. As expected, DNA from transgenic mice gave the 5.6-kb *Bam*HI or 5.1-kb *Pvu*II band characteristic of the C57BL/6-derived, defective E_α^b gene (Fig. 1). In addition, DNA from transgenic mice 2 and 18 gave the 6.1-kb *Bam*HI band and 5.6-kb *Pvu*II band diagnostic of the E_α^d gene, indicating that these mice have retained the injected BALB/c E_α^d gene. DNA from the third transgenic mouse, no.

Fig. 2 Expression of the I-E $^\alpha E_\beta$ antigens on lymphocytes and peritoneal monocytes of the transgenic mice. *a*, Mononuclear cells were prepared from peripheral blood of CB6F₁ and C57BL/6 mice and of mice 2 and 26 on a Ficoll-Hypaque gradient. Cells were incubated with the biotininated Y17 antibody, followed by fluoresceinated avidin and analysed with a fluorescence-activated cell sorter, FACS-440 (Becton-Dickinson). *b*, Spleen lymphocytes from CB6F₁, C57BL/6 mice and an offspring (no. 2-7) of mouse 2 were incubated with the Y17 antibody and fluorescein isothiocyanate (FITC)-conjugated anti-mouse μ chain, followed by phycoerythrin-conjugated avidin and analysed with a cell sorter. *c*, Peritoneal exudate cells were prepared from CB6F₁ mice and from the offspring of mouse 2 which had been injected intraperitoneally with 1 ml 3% proteose peptone 3 days earlier. Cells (1×10^6 in 1 ml) were incubated in a 24-well plastic plate at 37 °C and non-adherent cells were removed by washing with Hank's balanced salt solution. Adherent cells were cultured with or without 50% (v/v) supernatant of Con A-stimulated spleen cells for 2 days. This supernatant contains, respectively, 100 U ml⁻¹ and 650 U ml⁻¹ γ -interferon and interleukin-2 activity. The cells were then stained with the Y17 antibody and analysed with a cell sorter.

26, also displayed the 5.6-kb *PvuII* band but the size of the corresponding *Bam*HI fragment was somewhat greater than 6.1 kb. This discrepancy may result from loss of the 5' *Bam*HI site. From an approximate calculation based on the intensities of the E_α^d bands, mice 2 and 18 seem to have at least 10 copies of the E_α^d gene. These E_α^d genes were transmitted to a fraction of offspring, two examples of which (nos 2-7 and 2-10) are shown in Fig. 1. In the following studies, both the original transgenic mice and their offspring were used.

Expression of the E_α gene in the transgenic mice was examined by the surface staining of peripheral blood mononuclear cells and splenic lymphocytes using a monoclonal anti-I-E antibody, Y17 (ref. 13). Because this antibody can recognize combinations of E_α and E_β molecules of various haplotypes, including $E_\alpha^d E_\beta^b$, we could examine whether the product of the microinjected E_α^d gene can pair with the endogenous E_β^b chain and be displayed on the cell surface as the hybrid $E_\alpha^d E_\beta^b$ molecule. As shown in Fig. 2a, about one-third of the peripheral blood lymphocytes from mice 2 and 26 could be stained with Y17, indicating that the lymphocytes of the transgenic mice expressed the hybrid I-E^{d/b} antigen. The fluorescence intensity of the Y17-positive cells of the transgenic mice seems to be significantly higher than that of a CB6F₁ (C57BL/6 × BALB/c F₁) mouse. As expected, the I-E^{d/b} antigen was mainly expressed on B lymphocytes bearing immunoglobulin M (IgM) molecules on the cell surface (Fig. 2b). We also analysed E_α^d gene expression on the monocytes of the transgenic mice. Peritoneal monocytes of the transgenic and CB6F₁ mice, as the control, were cultured for 48 h with or without the culture supernatant of concanavalin A (Con A)-stimulated murine spleen cells containing 50 U ml⁻¹ of γ -interferon and stained with the Y17 antibody. As expected, the I-E^{d/b} molecules were detected on a very small fraction of the unstimulated cells and on most of the stimulated cells of the CB6F₁ mouse. In contrast, most of the peritoneal monocytes from the transgenic mice expressed the I-E^{d/b} antigen in the absence of the Con A supernatant and the addition of the supernatant to the culture media did not increase the level of I-E^{d/b} expression. The reason for this constitutive expression is unknown, but it may be related to the fact that the transgenic mice examined (nos 2-11 and 2-18) carry a large copy number (>20) of E_α^d genes. In any case, it is interesting that not only the injected E_α^d genes but also the endogenous E_β^b gene seem to be constitutively expressed in these mice.

Fig. 3 Northern blot analysis of E_α mRNA from various tissues of a transgenic mouse. Total RNA was phenol-extracted from spleen, liver, kidney and brain of a transgenic mouse and adsorbed to oligo(dT)-cellulose; 2 μ g poly(A)⁺ RNA from spleen and 5 μ g poly(A)⁺ RNA from liver, kidney and brain were denatured, electrophoresed on a 1% formaldehyde-containing agarose gel, transferred to a nitrocellulose filter and hybridized with a ³²P-labelled 3.5-kb *SalI* fragment containing exons 2, 3 and 4 of the E_α gene as described previously³³. As a control, 2 μ g mRNA from C57BL/6 spleen was also analysed. Sizes of RNA molecules are shown in kilobases.

To examine the transcription of the microinjected E_α^d gene, we performed a Northern blot analysis of the E_α transcript in various tissues from a transgenic mouse, no. 2-10. Figure 3 shows that detectable amounts of E_α messenger RNA of 1.25 kb were observed in poly(A)⁺ RNA from all analysed tissues of the transgenic mouse. The microinjected E_α^d gene seemed to be transcribed at a low level in liver and brain cells. Although kidney cells of a transgenic mouse contained a relatively large amount of E_α mRNA, similar amounts of E_α transcripts were also observed in BALB/c kidneys (data not shown). The class II antigens are known to be expressed on B lymphocytes and macrophages in lymphoid organs^{1-3,14}, liver Kupffer cells^{15,16}, brain astrocytes¹⁶, kidney pelvis cells¹⁵ and blood vessel endothelial cells¹⁷. The observed transcripts of the E_α gene in tissues of the transgenic mouse may be due to these cells. Recently, a rabbit β -globin gene was reported to be expressed in skeletal muscle and testis but not in erythroid cells in transgenic mice¹⁶. Immunoglobulin μ heavy-chain genes were also expressed in heart as well as in lymphocytes¹⁹. We cannot

Table 1 I-E^{d/b} antigen in a transgenic mouse is functional in terms of induction of a mixed lymphocyte reaction and restoration of the response to GL-Phe

Transgenic	—	—	—	—	4,434 (±438)	15,228 (±4,612)	5,846 (±306)	20,314 (±5,061)
CB6F ₁	—	—	—	—	5,530 (±865)	25,363 (±1,067)	5,160 (±1,580)	58,340 (±22,137)

2.5 × 10⁵ responder lymph node cells from normal C57BL/6 mice were stimulated with 1 × 10⁶ mitomycin C (MMC)-treated cells from C57BL/6, CB6F₁ or transgenic mice in 0.2 ml complete culture medium in a microtitre plate (Falcon 3072, Becton-Dickinson) for 4 days. Complete culture medium consisted of RPMI 1640 culture medium, 10% heat inactivated fetal calf serum (FCS), 5 × 10⁻⁵ M 2-mercaptoethanol, 100 mM HEPES, 100 U ml⁻¹ penicillin, 100 μ g ml⁻¹ streptomycin and 2 mM glutamine. MMC treatment of stimulator cells: 5 × 10⁶ spleen cells were incubated in 1 ml complete culture medium in the presence of 50 μ g MMC at 37 °C in 5% CO₂ in air; after 30 min, cells were washed three times with Hank's balanced salt solution. Cells were pulsed with 1 μ Ci ³H-TdR for the final 16 h of culture. Cells were collected on a filter paper with a semi-automatic cell harvester (Labo Mash Science, Tokyo) and the uptake of ³H-TdR was measured by standard scintillation counting. The proliferative responses of responder cells are expressed as the uptake of ³H-thymidine (mean ± s.d. of triplicate cultures). The antigen-specific T-cell proliferative response was assayed according to the methods of Corradin *et al.*³¹. C57BL/6 mice (three in one group), CB6F₁ mice (three in one group) and a transgenic mouse were immunized with 50 μ g GL-Phe (given by Dr R. Schwartz, NIH) and emulsified in the complete Freund's adjuvant. After 1 week, draining lymph nodes were removed and single-cell suspensions made. Cells were cultured in complete culture medium containing 10% heat-inactivated horse serum instead of FCS in the presence of 200 μ g ml⁻¹ GL-Phe, 100 μ g ml⁻¹ KLH or 50 μ g ml⁻¹ purified protein derivative (PPD) from *Mycobacterium tuberculosis* (Mitui Pharmaceuticals, Tokyo). Cells were cultured for 4 days and the proliferative response assayed as described above.

exclude the possibility that the microinjected E_d^d genes are expressed in inappropriate cells of the transgenic mouse. To assess this possibility more precisely, further studies, including *in situ* RNA hybridization using tissue samples, are required.

Finally, we examined whether the newly expressed I-E^{d/b} antigen has immunological functions. Spleen cells of the transgenic mice could induce a significant proliferation of C57BL/6 lymphocytes (Table 1), suggesting that the I-E^{d/b} antigens of the transgenic mice could be successfully recognized as allo-antigens by the T lymphocytes from C57BL/6 mice. It is known that mouse strains of *H-2b*, *s*, *f* and *q* haplotypes do not respond to certain antigens such as GL-Phe, GL-Leu and pigeon cytochrome *c* (*Ir* gene phenomena)²⁰⁻²²; this unresponsiveness is correlated with the defect in I-E antigen expression in these strains²³. We therefore used responsiveness to GL-Phe as another criterion for the functional expression of the I-E^{d/b} antigens in the transgenic mice, and attempted to demonstrate directly that the *I-E* gene defect is the cause of the unresponsiveness. For this purpose, lymph node cells from mice primed with GL-Phe in complete Freund's adjuvant were assayed for a proliferative response to GL-Phe and, as a control, to keyhole limpet haemocyanin (KLH). We found that GL-Phe could induce significant proliferation of the lymphocytes from CB6F₁ mice (positive control) and from the transgenic mouse but not of lymphocytes from C57BL/6 mice (negative control) (Table 1). The proliferation was specific to the priming antigen (GL-Phe) because no proliferation above the background level was observed in the presence of KLH. These results suggest strongly that the product of the microinjected E_d gene is expressed on the surface of the antigen-presenting cells of the host mouse (C57BL/6) in such a way as to allow the restoration of responsiveness to the antigen GL-Phe.

In the past, several groups have successfully introduced cloned genes for major histocompatibility antigens into cultured cell lines²⁴⁻²⁶, and these transformants have been used to study antigen recognition by T lymphocytes²⁷⁻³⁰. However, this approach is not suitable for *in vivo* analysis of the roles of the major histocompatibility antigens in the generation of the diversity of T-lymphocyte repertoires. To date, this latter type of analysis has been carried out by using H-2 congenic mice, chimaeric mice and H-2 mutant mice. In the present study, we produced transgenic mice which express functional I-E antigens by microinjecting the cloned E_d^d DNA into fertilized eggs of C57BL/6 mice. These transgenic mice have several advantages over the aforementioned mice: (1) the transferred, cloned gene is well characterized; (2) a cloned gene can be modified by *in vitro* mutagenesis or exon shuffling; (3) it is possible to establish new strains carrying the E_d^d gene by crossing these mice with other B6 or B10 congenic mice. Thus, these transgenic mice should be a powerful tool for the analysis of the effect of well-defined class II genes on immune responses.

This study was supported by grants from the Ministry of Education, Science and Culture of Japan (to T.K.), the American Cancer Society (NP-372 to S.T.), US NIH (AI-17879 to S.T.) and the US-Japan Science Cooperation Program sponsored by NSF and JSPS (to S.T. and T.K.).

Human T-lymphotropic virus type III (LAV, HTLV-III)^{1,2} is aetiologically linked to acquired immune deficiency syndrome (AIDS) and persistent general lymphadenopathy (PGL)²⁻⁷. Specific radioimmunoassays (RIA), enzyme-linked assays, immunofluorescence assays (IFA) and immunoblotting techniques are being used widely to detect serum antibodies to HTLV-III in infected patients and in those at risk of infection⁴⁻⁷. However, these assays do not functionally identify those antibodies that neutralize the infectivity of the virus. We have used three methods of titrating serum neutralizing factors: inhibition of syncytium induction, neutralization of envelope pseudotypes of vesicular stomatitis virus (VSV) and reduction of infectivity of HTLV-III for a cell line permissive to virus replication. We report here that sera from subjects in various disease categories possess only low-level neutralizing activity, even when antibodies to viral membrane antigens are present in high titre. Envelope pseudotypes prepared from four HTLV-III isolates made in three different countries are equally sensitive to neutralization by positive sera, including sera from patients yielding two of the virus isolates.

To examine neutralizing properties of sera containing anti-HTLV-III, we initially determined whether such sera would inhibit the induction of syncytia or would neutralize VSV(HTLV-III) pseudotypes. When uninfected cells bearing HTLV-III receptors are mixed in excess with virus-producing cells, large multinucleated syncytia form within 6 h and are an indicator of viral envelope glycoprotein activity⁸. From previous studies⁹⁻¹² of HTLV-I and HTLV-II, we would expect antibodies binding to the functional epitopes of the viral envelope antigen both to inhibit syncytium formation and to neutralize the infectivity of pseudotypes.

Table 1 shows the mean titres of sera from patients naturally infected with one of the three known HTLV strains. As expected, sera containing antibodies to HTLV-I and HTLV-II specifically inhibited syncytium formation induced by these viruses and also

showed high titres of neutralizing activity specific for the respective VSV pseudotypes. In contrast, sera containing anti-HTLV-III showed negligible neutralizing activity even though the antibody titre for IFA antibody to cell-surface HTLV-III antigens was as high or higher than the IFA titres to HTLV-I and HTLV-II membrane antigens displayed by sera containing antibodies to the respective viruses. None of the 12 sera containing anti-HTLV-III showed significant syncytium inhibiting activity; there was slight inhibition of pseudotype plaques by six of the sera, but none had a neutralizing titre greater than 1:50. When sera containing high-titre neutralizing activity to HTLV-I or HTLV-II were tested for neutralization of VSV(HTLV-III), no cross-reaction was detected.

Because the sera containing anti-HTLV-III were from patients with symptoms of the AIDS-related complex, we sought to determine whether asymptomatic, yet seropositive, individuals have stronger neutralizing activity. The results of VSV(HTLV-III) neutralization tests on 97 positive sera (79 from the United Kingdom⁷ and 18 from Africa¹³) are shown in Table 2, categorized according to the clinical status of the patient, or his or her origin. At 1:10 dilution, only 15% of the sera exhibited neutralization of 80% or more VSV(HTLV-III) plaque-forming units (PFU), and these were mainly British or African patients with PGL. However, when a reduction of 40% PFU was taken as a positive score, then the sera of 69% patients from all clinical groups were found to contain neutralizing factors. The neutralizing activity was completely absorbed by protein A of *Staphylococcus aureus* (data not shown), indicating that it was a property of serum immunoglobulins.

The pseudotype neutralization tests had been performed using the American HTLV-IIIB isolate growing in HT-H9 cells¹⁴ as a source of envelope antigen for the VSV pseudotypes. As genomic polymorphisms have been observed, including variation in the putative *env* gene¹⁵, it seemed plausible that the very weak neutralization observed with British and African sera reflected divergence of envelope antigenicity resulting from the spread of HTLV-III through different host populations. Therefore, we prepared VSV(HTLV-III) pseudotypes with the envelope antigens of four reportedly independent HTLV-III isolates, and titrated neutralizing activity in selected sera including two (Bru and Arg) from patients from whom virus isolates (LAV-1 and CBL-1 respectively) had been made. Serum samples from the British patient Arg were available from before and after the date of biopsy leading to isolation of CBL-1.

Table 3 shows that the sera tested had similar neutralizing titres for VSV pseudotypes with the envelopes of French, British and American HTLV-III isolates. The sera did not have significantly stronger neutralizing activity for their homologous virus isolate. Thus, the relatively low neutralizing titres of sera containing anti-HTLV-III would not seem to be directly attributable to strain variation. When four positive sera were combined, the neutralizing titre was no higher than that of the strongest serum in the pool. Furthermore, an American commercial immunoglobulin G preparation, pooled from several hundred sera selected for hepatitis B virus antibodies and possessing high anti-HTLV-III by RIA, contained barely detectable neutralizing antibodies (Table 3).

It may be argued that the low neutralizing titres of sera containing anti-HTLV-III assayed by syncytium inhibition and by pseudotype inactivation do not reflect the sensitivity to neutralization of HTLV-III itself. We therefore compared the effect on HTLV-III infectivity of four sera previously found to have high IFA titres and relatively strong, weak or undetectable neutralizing activity for VSV(HTLV-III) pseudotypes. Table 4 shows that the neutralizing titres for infectious units of HTLV-III and of VSV(HTLV-III) were closely parallel, although inactivation of HTLV-III may be slightly more sensitive. Low-titre neutralizing activity of human sera to HTLV-III is also being reported by others^{16,17,36,37}. Thus, the rapid and quantitative VSV pseudotype neutralization test serves as an accurate estimate of the protective effect of sera in neutralizing HTLV-III infectivity.

Table 1 Mean titres of human sera from subjects infected with HTLV types I, II or III assayed by different methods

Virus	No of sera	Competitive RIA	Membrane IFA	Syncytium inhibition	Pseudotype neutralization
HTLV-I	9	1,216	2,250	180	3,257
HTLV-II	4	774	2,500	825	3,750
HTLV-III	12	1,272	2,847	<10	<10

Human sera known to be positive by RIA for antibodies to HTLV-I, -II or -III were titrated after heat inactivation (56 °C for 30 min) by methods described previously^{7,10-12}. Values are the geometric means of the reciprocals of the highest serum dilution giving >50% inhibition radioimmunoassay (RIA), >80% fluorescing cells (IFA) and >80% reduction of nuclei in syncytia or of PFU of VSV pseudotype. For both syncytial and pseudotype assays of HTLV-I and HTLV-II, Human osteosarcoma (HOS) cells were used as indicator cells¹¹. JM cells served as indicator cells for syncytial assays of HTLV-III⁸, adherent CEM cells pretreated with 25 µg ml⁻¹ DEAE-dextran were used for assay of VSV(HTLV-III) pseudotypes, and were subsequently overlaid with HOS cells and then agar medium, as described previously⁸.

Table 2 Neutralization of VSV(HTLV-III) pseudotype by sera of subjects positive by RIA

Serum donor	No of sera	No of sera reducing VSV(HTLV-III) plaques by	
		>40%	>80%
AIDS, KS	6	6	1
AIDS, OI	6	2	0
PGL only	13	12	4
PGL plus minor OI	4	4	2
Contacts of AIDS or PGL	9	7	2
Symptomatic homosexuals	8	6	1
Asymptomatic			
homosexuals	11	6	0
Haemophiliacs	22	11	0
Africans with KS or PGL	18	13	4
Total seropositives	97	67	14
Seronegative controls	20	0	0

Heat-inactivated sera were incubated at 1:10 dilution with 5×10^2 PFU VSV(HTLV-III) for 1 h at 33 °C and surviving PFU were plated on adherent CEM cells as described for Table 1. Positive sera taken in the United Kingdom were selected from a previous study⁷, as were the uninfected control sera. Africans with Kaposi's sarcoma (KS) or PGL were Zambians¹³. Patients with AIDS were identified clinically as opportunistic infection (OI) and/or KS according to the US Centers for Disease Control definition. Patients with PGL had enlarged lymph nodes (>1 cm) in two or more extra-inguinal sites persisting for more than 3 months according to the Centers for Disease Control definition. Two patients had oral candidiasis, one developed a lung abscess following aspiration during an epileptic fit. One patient developed AIDS 12 months after the serum specimen was taken. AIDS and PGL contacts were the regular sexual partners for at least 6 months before diagnosis of AIDS or PGL in their partner. All were well and without lymphadenopathy. Symptomatic homosexuals included six patients with recent viral-like illnesses accompanied by lymphadenopathy (4), pharyngitis (2) and an unexplained transient erythematous macular rash (1), one patient with generalized lymphadenopathy and malaise of <3 months' duration and one patient with a streptococcal pneumonia. Asymptomatic homosexuals were men attending the clinic with no systemic symptoms or generalized lymphadenopathy. Haemophiliacs had received regular clotting factor replacement therapy. Neutralization tests were performed and scored 'blind', that is, without knowledge of RIA titres or clinical status of the patient.

The low titres of virus neutralizing antibodies in subjects infected with HTLV-III contrasts with the type-specific, high-titre human humoral response to HTLV-I and HTLV-II⁹⁻¹², and also differs from the immune response of animals naturally infected with avian¹⁸, feline¹⁹ and bovine²⁰ leukaemia viruses. HTLV-III is morphologically more closely related to the lentivirus family of retroviruses, reportedly exhibiting weak cross-reaction of antibody to the core antigen of equine infectious anaemia virus (EIAV)²¹, and partial genomic homology to visna virus (VV)²². Strongly neutralizing sera are commonly detected in animals infected with EIAV^{23,24} and VV^{25,26}, although neutralizing activity has not been found in goats infected with

Table 3 Neutralization of VSV pseudotypes with envelopes of different HTLV-III isolates including matched sera

Serum donor	LAV-1 (France)		Titre neutralizing VSV(HTLV-III) plaques (%)				IIIA (USA)	
	40	80	CBL-1 (UK)		IIIB (USA)		40	80
Bru (LAV-1)	50	10	50	10	50	10	50	10
Arg (CBL-1) October 1983	50	<10	25	<10	50	<10	50	<10
Arg (CBL-1) September 1984	50	<10	50	<10	50	<10	50	<10
Neb	50	10	50	10	50	10	50	10
Sel	250	50	250	50	250	50	250	50
Pooled IgG (USA)	50	<10	50	<10	50	<10	50	<10
Uninfected control	<10	<10	<10	<10	<10	<10	<10	<10

VSV pseudotypes were prepared with four isolates of HTLV-III and plated on adherent CEM cells (Table 1) following incubation with the sera indicated. The CBL-1 isolate was made from a lymphomatous lymph node biopsy taken from AIDS patient Arg in June 1984, 8 months after the first serum sample and 3 months before the second serum sample assayed (A.G.D., A. Horwich, M. G. Peckham and R.A.W., unpublished data); this patient was a homosexual living in the United Kingdom with a single sexual partner who was also seropositive. Serum Bru was taken from a PGL patient at the time of virus (LAV-1) isolation¹. Fivefold serial dilutions of sera were made and the reciprocal of the highest dilution causing >40 and >80% reduction of pseudotype PFU are tabulated.

Table 4 Neutralization of HTLV-III infectivity by selected human sera

Donor	Serum Membrane IFA titre	Surviving infectious units after antiserum treatment	
		HTLV-III	VSV(HTLV-III)
Control	0	5,000	5,000
Arb	1,250	500	500
Neb	2,500	50	500
Sel	2,500	<50	<10
Dol	1,250	5,000	5,000

Neutralization of infectivity of HTLV-III was measured by end-point titration of surviving virus after adding 1:10 dilution of antiserum to 5,000 infectious units of virus stock (cell-free culture supernatant) for 1 h at 33 °C. Duplicate flasks of HT-H9 cells¹⁴ were infected with serial 10-fold dilutions of the treated virus in the presence of 25 µg ml⁻¹ DEAE-dextran. The cells were maintained and passaged in growth medium and the percentage of cells immunofluorescent for HTLV-III membrane antigens using a known human serum assayed on days 7, 10, 13 and 18 post-infection. The cells in each flask were also tested for virus production by syncytium-inducing activity in JM cells, with similar or slightly more sensitive results than IFA. The end-point titre at 18 days (taking >10% fluorescent cells as positive) was used to calculate the surviving units of HTLV-III infecting the HT-H9 cells following antiserum treatment. The surviving plaques of VSV(HTLV-III) after similar serum treatment of 5,000 pseudotype PFU were assayed on adherent CEM cells as described in Table 1 legend.

caprine arthritis encephalitis lentivirus (CAEV)²⁷. Considerable antigenic variation is observed with EIAV and VV; antibodies elicited early in infection of individual animals have a narrow specificity of neutralizing activity, allowing non-neutralizable virus variants to emerge²³⁻²⁶, whereas later sera can neutralize a broader range of virus variants²⁵.

Antigenic variation might explain the apparently low level of neutralization of HTLV-III by human sera. However, our preliminary data show that neither early nor late serum relative to HTLV-III isolation from one patient was strongly neutralizing, and that different virus isolates supposedly made in France, the United States and the United Kingdom did not vary significantly in sensitivity to neutralization by selected sera. Preliminary experiments using human or guinea pig complement indicate that complement does not markedly enhance the inactivation of VSV(HTLV-III) pseudotypes by weakly neutralizing sera, again reminiscent of CAEV (ref 27). This raises the question of the nature of the membrane antigens recognized by human sera on the surface of HTLV-III-infected cells, which is under investigation using biochemical and immunoelectron microscope techniques.

The CD4 (T₄) cell-surface antigen is an essential and specific component of the HTLV-III receptor^{8,28}. Because neutralizing antibodies generally bind to those epitopes of retrovirus envelope glycoproteins that interact with receptors^{29,30}, the low

neutralizing response might be explained by molecular mimicry between the HTLV-III glycoprotein epitopes and an endogenous cellular antigen that normally interacts with CD4. Class II major histocompatibility complex (MHC) antigens (for example, HLA-DR) expressed on activated B cells and on antigen-presenting cells are thought to interact with CD4 antigen during the helper immune functions of CD4-positive cells^{31,32}, but we have not yet observed any anti-MHC class II antibodies that neutralize VSV(HTLV-III) pseudotypes.

Although we found no clear pattern of neutralization response among nearly 100 infected subjects, a larger proportion of PGL patients had detectable neutralizing sera than either AIDS patients or healthy seropositive individuals. The low neutralization titres may explain why patients seropositive by other techniques behave as infective carriers through sexual contact³³ or blood transmission^{34,35}. It is important to understand more about the parameters of HTLV-III neutralization for the development of effective vaccines. It remains to be seen whether HTLV-III envelope antigen manufactured by recombinant DNA techniques will yield a more powerfully protective immunogen than is apparent in humans exposed to live virus.

We thank M. Exley and A. Smith for technical assistance; members of the Middlesex/University College Hospitals AIDS Research Group for sera from carefully categorized homosexual patients; S. Ball, L. Luzzatto and P. Kernoff for haemophilic sera; A. C. Bayley and R. G. Downing for Zambian PGL and KS sera; M. Popovic, R. C. Gallo, L. Montagnier and J.-C. Chermann for American and French HTLV-III isolates; and L. Montagnier for serum Bru. This study was supported by the Wellcome Trust, MRC and the Cancer Research Campaign.

HTLV-III-neutralizing antibodies in patients with AIDS and AIDS-related complex

Marjorie Robert-Guroff, Monica Brown & Robert C. Gallo

Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Maryland 20205, USA

The isolation of the human T-cell leukaemia (lymphotropic) virus type III (HTLV-III or lymphadenopathy-associated virus) from cells of many patients with acquired immune deficiency syndrome (AIDS)^{1,2} presented the first evidence that the virus was the aetiological agent of the disease. Subsequent seroepidemiological studies have shown the presence of HTLV-III-specific antibodies in the serum of most patients with AIDS and AIDS-related complex (ARC)^{3,4}, and in the serum of many individuals at risk for AIDS⁵⁻¹⁴. Despite these extensive studies, there are no reports of protective effects of HTLV-III antibodies. In contrast, neutralizing antibodies specific for HTLV-I and -II have been identified previously¹⁵. Therefore, we investigated whether HTLV-III-exposed individuals possess antibody activities capable of inhibiting viral infection (see also refs 16, 17). Here, we report that natural antibodies capable of neutralizing HTLV-III infection of H9 cells were detected in most adult AIDS and ARC patients but in no normal healthy heterosexual controls. Geometric mean antibody titres in ARC patients were double those in AIDS patients, and were even higher in two antibody-positive healthy homosexuals. This suggests that virus neutralizing antibodies may exert an *in vivo* protective effect. The presence of these antibodies indicates an immunological response to HTLV-III which potentially may be manipulated for therapeutic advantage. The methodology used here will be useful in monitoring future vaccine approaches.

We used the H9 clone of the HT cell line¹ as a target for cell-free HTLV-III infection and initially analysed several sera for virus neutralizing activity. Infection of H9 cells was assessed by monitoring expression of HTLV-III p24 using a monoclonal antibody¹⁸ in an indirect immunofluorescence assay. Figure 1a illustrates the kinetics of infection of H9 cells with HTLV-III virus preincubated with sera positive or negative for virus neutralizing activity. By 3 days post-infection, ~80% of the H9 cells incubated with HTLV-III pretreated with control serum were infected, as indicated by their expression of HTLV-III p24. In contrast, only 10% of H9 cells expressed HTLV-III p24 at day 3 when infected with virus pretreated with serum from a patient with ARC. That inhibition of infection was mediated by a viral rather than a cellular antigen was suggested by ready infection of H9 cells with HTLV-III following pretreatment of the cells rather than the virus with the same sera (Fig. 1a). The inhibitory activity of certain sera was not simply a nonspecific effect of high serum concentrations because the activity was titratable (Fig. 1b).

We also detected neutralizing activity by other criteria. For example, two serum dilutions giving 95 and 90% neutralization

Fig. 1 *a*, Kinetics of infection of H9 cells in the presence of human serum. Sera from a normal healthy heterosexual (○) and from a patient with ARC (●). In a parallel experiment, the same sera were preincubated with H9 cells for 1 h at 4 °C. Cells were washed with PBS, incubated with the cell-free HTLV-III preparation, and cultured as described below. Results of this treatment of the H9 cells with sera are represented by the normal, healthy heterosexual serum (△) and the serum of the patient with ARC (▲). *b*, Titrations of representative human sera for virus neutralizing antibody activity. Representative titrations are shown for two sera negative for viral neutralizing antibody activity: a patient with AIDS (○) and a patient with ARC (□). Representative sera positive for virus neutralizing antibody were obtained from a paediatric AIDS case (●), a patient with ARC (■), a healthy homosexual (△) and an adult AIDS patient (▲). All values obtained were normalized to the level of infection attained in the presence of a standard antibody-negative serum.

Methods. *a*, Media containing 2.5×10^8 HTLV-III particles per ml were collected from H9/HTLV-III cells. Following removal of the cells by low-speed centrifugation, the virus-containing supernatant was centrifuged for 3 h at 32,000g in a Beckman type 35 rotor. Viral pellets were resuspended in a total volume of 2.25 ml media (RPMI 1640 containing 20% fetal calf serum and penicillin/streptomycin). Uninfected H9 cells were washed in media and incubated for 20 min at room temperature in media containing $2 \mu\text{g ml}^{-1}$ polybrene. Cells were washed and resuspended at a concentration of $4 \times 10^6 \text{ ml}^{-1}$. Sera to be tested were heat inactivated at 56 °C for 30 min and filter sterilized. For each assay, 20 μl virus suspension and 20 μl of a 1:2 dilution of serum were mixed and incubated in a microtitre plate for 1 h at 4 °C and 15 min at room temperature. H9 cells (10 μl) were added to each well and incubation continued for 1 h at 37 °C. Aliquots (15 μl) of each mixture were plated into 200 μl media in duplicate wells of another microtitre plate. Cultures were incubated at 37 °C in an incubator in which the CO_2 concentration was maintained at 5%. At the indicated time periods, cultures in individual wells were removed, washed twice with PBS and once with 1:1 PBS/water. Cells were suspended in ~30 μl of the same solution and 5-10- μl aliquots were spotted on eight-well toxoplasmosis slides. The spots were air-dried and the cells fixed for 10 min in 1:1 methanol/acetone at room temperature. Slides were stored at -20 °C before the assay. Viral infection was monitored by indirect immunofluorescence assay as described previously²⁴ on the fixed cells using ascites fluid containing monoclonal antibody BT3 (Biotech Research Laboratories) specific for HTLV-III p24 at a dilution of 1:200. Ascites fluid derived from mice inoculated with P3 $\times$ 63 cells was used as a negative control at a similar dilution. A fluorescein isothiocyanate conjugated F(ab')₂ fragment of sheep anti-mouse IgG was used as second antibody. Per cent fluorescent cells was determined following counts of at least 100 cells on each duplicate preparation. *b*, Sera were diluted in media as indicated and assayed as for *a*. Viral infection, monitored by expression of HTLV-III p24 in the indirect immunofluorescent assay, was determined at 3 days post-infection

when monitored using monoclonal anti-p24 gave 89% and 95% inhibition, respectively, when monitored using a specific monoclonal antibody to HTLV-III p15 (ref 18). Measurement of reverse transcriptase activity in proportionately increased cultures showed that the same samples neutralized viral infectivity on day 3 by 62% and 51% and on day 7 by 76% and 54%. Our system was optimized for detection of viral p24 expression in

Table 1 HTLV-III neutralizing activity is a property of IgG and is directed against a viral antigen

IgG was purified from 0.5-ml aliquots of human serum by absorption to protein A-Sepharose equilibrated in phosphate-buffered saline (PBS). Following extensive washing of the columns with PBS, IgG was eluted with 0.1 M glycine-HCl, pH 2.8. The eluate was neutralized with 2 M Tris-HCl, pH 8.0, dialysed extensively against 10 mM ammonium bicarbonate and lyophilized. The purified fractions were dissolved in 0.5 ml PBS, filter sterilized and diluted in media for titration of neutralizing antibody activity as described in Fig. 1 legend. For virus absorption experiments, 62 ml cell-free virus supernatant containing 2.5×10^8 virus particles per ml were pelleted as described in Fig. 1 legend. The viral pellet was resuspended in 100 μ l of a 1:10 dilution of serum to be absorbed and incubated overnight at 4 °C. The virus was again pelleted by centrifugation and the absorbed serum was saved for titration of virus neutralizing antibody activity. Sera were similarly absorbed on pellets of washed 10^7 cells and titrated.

* Values for % HTLV-III p24-positive cells were normalized to the level of infection obtained in the presence of a standard negative serum treated similarly to the test serum. Antibody titres were then expressed as the reciprocal of the serum dilution at which virus infection was 60% of that obtained in the presence of this standard negative serum.

cells washed free of extracellular virus. The enzyme levels in culture fluids reflected not only activity in newly released virus, but also residual activity from the large virus inoculum. Ideally, precise quantitation of neutralization by enzyme assay would require a limiting inoculum and assay after 10–14 days of culture. Nevertheless, the decrease in reverse transcriptase activity obtained substantiated our hypothesis that positive sera blocked infectivity and did not simply alter p24 detection. In subsequent experiments, we assessed infectivity by p24 expression.

Serum immunoglobulins were purified on protein A-Sepharose columns and assayed for virus neutralizing activity. The serum activity capable of inhibiting viral infection resided in the IgG fractions (Table 1), indicating that the activity is immunoglobulin mediated. It is unlikely that these fractions are contaminated extensively with viral envelope capable of competing for viral receptors, or with some other non-immunoglobulin factor, but we have not eliminated these possibilities. To confirm that the inhibitory activity was directed against a viral, rather than a cellular, antigen, sera were absorbed with preparations of cell-free virus or with infected or uninfected H9 cells. Although absorption with cells had little effect, absorption with viral preparations effectively removed the inhibitory activity of positive sera (Table 1). The fact that similar titres were obtained following absorption with infected and uninfected H9 cells suggests that viral antigenic determinants involved in the neutralizing antibody response are masked or presented in a

Table 2 HTLV-III neutralizing antibody in AIDS, ARC and other at-risk patients

Serum source	HTLV-III-neutralizing antibody			Geometric mean titre $\pm$ s.e.m.
	No positive/no tested	% Positive	Range of titre	
Adult AIDS patients	21/35	60	10–520	44 $\pm$ 10
Paediatric AIDS patients	3/9	33	80–180	117 $\pm$ 28
Adult ARC patients	28/35	80	17–560	88 $\pm$ 16
Healthy homosexuals*	2/12	17	130–340	210 $\pm$ 101
Healthy heterosexuals	0/20	0	—	—
Heterosexual partners of AIDS patients†	1/3	33	78	—
Mothers of paediatric AIDS patients‡	0/2	0	—	—
Siblings of AIDS patients	1/2	50	55	—
Patients with acute mononucleosis	1/4	25	13	—
Patient with sarcoidosis	0/1	0	—	—

All sera were screened for virus neutralizing antibody at a 1:10 dilution. Those sera possessing activity were further titrated as described in Fig. 1 legend. Antibody titre is defined in Table 1 legend.

* Two of the 12 sera were also positive for HTLV-III antibodies by enzyme-linked immunosorbent assay and Western blot assay³. A third serum showed weak reactivity with p24.

† All three individuals were positive for HTLV-III antibodies.

‡ Sera from these two foster mothers were negative for HTLV-III antibodies.

|| The positive sibling was also positive for HTLV-III antibody.

different conformation on virus-infected cells compared with mature virions.

Having defined a system able to detect HTLV-III neutralizing antibodies, we analysed sera from additional patients (Table 2). A high prevalence of patients with either AIDS or ARC possess virus neutralizing antibodies, in contrast to healthy heterosexual individuals in whom no such activity was demonstrated. Although neutralizing antibody titres ranged upwards of 500 for both groups of patients, overall titres were low, but ARC patients possessed a twofold higher geometric mean antibody titre compared with that of the AIDS patients. Moreover, among healthy homosexuals at risk for AIDS, the geometric mean antibody titre (determined on only two antibody-positive individuals, and therefore not appropriate for statistical analysis) was higher than that of either of the two patient groups. Whether this trend of higher titre with less disease manifestation will be substantiated, whether it suggests a protective effect of the neutralizing antibodies, or whether it signifies a general decline in antibody titre with progression of the disease requires further investigation.

Although the number of cases examined was small, paediatric AIDS patients positive for neutralizing antibodies had elevated titres compared with those of adult AIDS patients. This difference may reflect different criteria used in diagnosing paediatric and adult AIDS cases. Among miscellaneous cases, we detected neutralizing antibodies in the serum of a heterosexual partner of an AIDS patient and in the serum of a sibling of an AIDS patient. HTLV-III neutralizing antibody activity was not detected in any healthy heterosexual individuals (Table 2). However, a very low titre was obtained in one of four serum samples from patients with acute mononucleosis. This result suggests some weak cross-reactivity with viral antigen in sera possessing high levels of heterophilic antibodies.

In other retroviral systems, the major envelope glycoprotein is the target for neutralizing antibody^{19,20}. We anticipate this will also be the case here, and studies are under way to define the antigen recognized. Whether these virus neutralizing antibodies lead to *in vivo* protection, and whether they will be relevant to future vaccine approaches, are yet to be determined. Knowledge of other retroviruses leads to the question of whether the role of HTLV-III neutralizing antibody is similar to that in the visna virus system, where infection is persistent and the resultant disease is slowly progressive. Neutralizing antibodies elicited by visna virus have a narrow range of specificity and exert a selective pressure, leading to replication of non-neutralized mutant viruses during the course of the disease²¹. This

mechanism may be relevant to AIDS because HTLV-III isolates have shown a range of genomic variability, especially in the envelope region²², and a relatedness of HTLV-III to visna virus was demonstrated recently²³. It will be necessary to obtain serial isolates and serum samples from individuals throughout the course of the disease to determine whether HTLV-III neutralizing antibodies exert selective pressure on viral mutants.

The presence of HTLV-III neutralizing antibodies in sera of individuals exposed to HTLV-III demonstrates an immunological response during the course of disease development which may be used therapeutically. Furthermore, it gives hope that appropriate vaccine approaches may be effective in preventing viral infection. Further studies will determine whether virus neutralizing antibodies in the sera of patients have prognostic value or will be indicative of appropriate treatment regimes.

We thank Dr M. V. O'Shaughnessy for helpful discussion, Dr R. E. Tarone for statistical analysis and Ms Anna Mazzuca for assistance in preparing the manuscript.

Département de Pathologie CMV, 1211 Genève 4, Switzerland

Schistosomiasis is a parasitic infection of man which is widespread in tropical countries, and which so far has resisted attempts at control. We have been approaching the problem from an immunological angle. We have previously reported¹ the production of a rat monoclonal IgG2a antibody against *Schistosoma mansoni* which exhibits marked cytotoxicity for schistosomula in the presence of eosinophils and a high degree of protection by passive transfer in naive rats. This antibody, IPLSm1, was shown to bind specifically to a schistosomulum membrane target antigen defined as a glycoprotein of relative molecular mass 38,000 (38K)², which is strongly immunogenic in schistosome infection of various animal species including man³. Although theoretically the 38K protein represents an excellent candidate for a potential vaccine against schistosomiasis, the glycanic nature of the epitope recognized by

IPLSm1 limits its production by DNA recombinant technology. It was, moreover, shown that, together with protective antibodies, the 38K molecule was able to induce the production of blocking IgG2c antibodies that inhibit the functional properties of IPLSm1 both *in vitro* and *in vivo*⁴. Therefore, following Jerne's network theory⁵, we considered an alternative approach, the possibility of immunization using anti-idiotypic antibodies. In the present study, rat monoclonal anti-idiotypic antibodies were produced against IPLSm1 (AB₁). Anti-idiotypic antibodies (AB₂) were selected by their capacity to inhibit the binding of radioiodinated AB₁ to its 38K target antigen. Sera from naive LOU rats immunized with a purified AB₂ preparation contained specific anti-schistosome antibodies (AB₃) which bound to 38K. AB₃ antibodies were strongly cytotoxic for schistosomula in the presence of rat eosinophils and conferred highly significant protection by passive transfer. Most importantly, rats immunized with AB₂ demonstrated marked protection (50-80%) to a challenge infection.

Monoclonal antibodies to IPLSm1 were obtained in a homologous hybridization system. Male LOU rats were injected subcutaneously with 1 mg of purified IPLSm1 plus 1 mg of glutaraldehyde-aggregated human IgG in the presence of complete Freund's adjuvant. Two weeks later, the rats received a second injection of the same preparation. The immunization was completed by two subcutaneous injections of 1 mg of

Fig. 1 Inhibition of radiolabelled AB₁ antibody (IPLSm1 IgG2a antibody) to the 38K antigen. Experiments were performed on PVC microtitre plates precoated with C₃-109 IgM antibody (an *S. mansoni* rat monoclonal antibody which recognizes the 38K molecule but does not interfere with IPLSm1 binding). Each well of the PVC plates was coated with 100 µl of a 10 µg ml⁻¹ solution of C₃-109 IgM diluted with 10 mM phosphate-buffered saline (PBS), a procedure which gives better fixation of the 38K antigen. After 2 h, the plates were washed twice in PBS buffer and saturated for 30 min with 200 µl of a 2% bovine serum albumin (BSA) solution in PBS. The plates were then washed twice in PBS-0.1% BSA. A Nonidet P-40 extract of schistosomula was added (100 µl antigen solution containing 100 µg of protein). After 2 h exposure at 37 °C, plates were washed twice in PBS-0.1% BSA buffer. For the test, 50 µl of ¹²⁵I-labelled IPLSm1 IgG2a was incubated with 50 µl of sera at a dilution of 1/25 in PBS-0.1% BSA buffer for 1 h at 37 °C and for 16 h at 4 °C and the plates were then washed three times in PBS-0.1% BSA buffer. The wells were counted in a γ-counter. The percentage of IPLSm1 inhibition binding was calculated using the following formula: $a - b/a \times 100 = \% \text{ of inhibition}$, where $a = \text{c.p.m. obtained when } ^{125}\text{I-AB}_1 \text{ was incubated with } 50 \mu\text{l of PBS-0.1\% BSA buffer}$, and $b, \text{ c.p.m. obtained when } ^{125}\text{I-AB}_1 \text{ was incubated with } 50 \mu\text{l serum from a rat bearing a subcutaneous IPLSm1 hybridoma}$ (▨), 50 µl serum from a rat immunized with AB₂ (JM8-36) (▤), 50 µl serum from a rat immunized with normal IgM (□), 50 µl serum from a 4-week-infected rat (▧) or 50 µl of normal rat serum (▩) (mean of five duplicate experiments ± s.d.).

Fig. 2 Humoral response to AB₂ immunization *a*, Immuno-fluorescence tests; *b*, eosinophil-dependent cytotoxicity. Indirect immunofluorescence tests were performed¹ on deep-frozen sections of schistosomula (8 μ m) *S. mansoni* schistosomula were prepared by penetration of cercariae through abdominal mouse skin. Sera (tested at a dilution of 1/20 in 10 mM PBS) were collected from LOU/M rats immunized by JM8-36 (AB₂) antibody (▨) purified from ascitic fluid as described previously¹⁵. A 1-mg aliquot of the purified preparation in physiological saline was injected subcutaneously at 2-week intervals. Control sera were obtained from rats injected in the same conditions with the IgM fraction of normal rat serum (□). Eosinophil-dependent cytotoxicity was measured after 48 h contact of skin schistosomula, preincubated overnight with the sera at a final dilution of 1/16, with a rat eosinophil-rich population (40–60% eosinophils). The percentage cytotoxicity was compared at equivalent dilutions with control sera, normal rat serum (▨) or serum from rats infected for 4 weeks with *S. mansoni* (▩). All results correspond to a mean of two duplicate experiments $\pm$ s.d.

IPLSm1 and 1 mg of aggregated human IgG in incomplete Freund's adjuvant at 2-week intervals. The Ouchterlony test was used to select rats showing the highest responses and spleen cells from these animals were fused with cells from the IR983F rat myeloma cell line⁶ as described previously¹. The hybrid cell supernatants were screened for their ability to inhibit the binding of ¹²⁵I-labelled IPLSm1 to the 38K target antigen coated on a polyvinyl chloride (PVC) plate. From 200 hybrid cell supernatants obtained from two successive cell fusion experiments, we selected 29 supernatants inducing significant levels of inhibition (>70%).

Analysis of the immunological components of these hybrid cell supernatants by the Ouchterlony test revealed that in most cases (23/29) they contained antibodies of the IgM class. The inhibitory activity of hybrid cell supernatants on IPLSm1 binding to 38K strongly suggested that the antibodies produced were able to fix to an epitope of IPLSm1 which was close to or part of its antigen-combining site, indicating that AB₂ were paratope-induced antibodies bearing an internal image of the original epitope.

We next investigated the potential use of such antibodies to induce active immunization in naive LOU rats. Two questions in particular were studied: Is it possible to use AB₂ antibodies to induce the production of AB₃ antibodies which will reproduce the effector mechanism described previously *in vitro* both in experimental schistosomiasis⁷ and with AB₁ antibody, involving eosinophil-mediated cytotoxicity¹? Does this immunization lead to a significant protection of naive rats against a challenge infection?

To answer the first question, we followed the kinetics of the antibody response in naive LOU rats immunized with AB₂ antibodies. Successive injections of purified IgM anti-idiotype antibody (JM8-36) for 4 weeks elicited anti-schistosome antibodies (AB₃) which were detected by indirect immunofluorescence on cryopreserved *S. mansoni* schistosomulum sections. In all cases, the fluorescence reaction was observed at the surface

Fig. 3 Passive transfer of AB₃ antibodies. Serum (1 ml) collected from JM8-36 immunized rats (▨) or from rats immunized with normal IgM (□) was injected intravenously into LOU rats infected 4 h previously with 800 *S. mansoni* cercariae. Parasitic burdens were evaluated 3 weeks later by liver perfusion¹⁶. The number of worms obtained from these groups was compared with the parasite burden of rats injected with 1 ml of physiological saline (▨). Percentage protection was calculated by the formula $(a-b)/a \times 100$, where a = the number of worms recovered from the saline-injected control group and b = the number of worms recovered from rat injected with 1 ml of AB₃ serum.

level. These observations, suggesting a close correlation between the structure of the anti-idiotype antibody and an epitope present on the surface of *S. mansoni* schistosomula, were confirmed by competition of AB₁ by AB₃ on radiolabelled membrane preparations of schistosomula. AB₃ preparations strongly inhibited the binding of AB₁ to the 38K molecule, indicating a close specificity for the same epitope (Fig. 1).

We explored the biological activity of these AB₃ antibodies induced by anti-idiotype immunization by determining their possible participation in eosinophil-dependent cytotoxicity reactions against *S. mansoni* schistosomula. A significant level of cytotoxicity (70–90%) was observed, close to that mediated by a 4-week *S. mansoni*-infected rat serum (Fig. 2) or by the AB₁ monoclonal antibody itself¹.

The relevance of these *in vitro* findings was fully supported by the demonstration that passive transfer of AB₃ antibodies to naive rats resulted in a significant protection of these animals to a challenge infection by *S. mansoni* cercariae (Fig. 3).

Finally, we studied the direct protective effect of an anti-idiotype immunization. In two series of experiments involving 30 naive LOU rats, immunization with AB₂ resulted in 50–76% protection to a challenge infection (Fig. 4).

The work presented here clearly demonstrates that immunization with an anti-idiotype monoclonal antibody can reproduce several parameters of the acquired immunity observed in experimental rat schistosomiasis. First, immunization with AB₂ resulted in the production of specific anti-*S. mansoni* antibodies in animals which had never been exposed to the parasite antigen. The antibodies produced exhibited the same specificity for the 38K molecule as the original AB₁ monoclonal antibody used to produce the anti-idiotype antibody, suggesting that the AB₂ produced may represent an internal image of the original epitope. However, most importantly, such experiments raise the possibility of inducing a strong immunity against schistosomes, as shown by both active immunization and passive transfer experiments.

Fig. 4 Protective effect of JM8-36 immunization LOU rats immunized as described in Fig. 2 legend, giving positive immunofluorescence reactions and significant eosinophil-dependent cytotoxicity, were infected with 800 *S. mansoni* cercariae. Parasite burdens were measured 3 weeks later by liver perfusion¹⁶. The number of worms obtained from rats immunized with JM8-36 AB₂ antibodies (■) was compared with those obtained from control groups, that is LOU rats injected with physiological saline (▨) or with IgM purified from normal rat serum (□). The percentage of protection was calculated by the formula $(a-b)/a \times 100$, where a = the number of worms obtained from the saline-injected control group and b = the number of worms recovered from AB₂-immunized rats.

Thus, immunization with anti-idiotypic antibodies represents an alternative approach to immunization against pathogens. Although recent studies have produced encouraging results⁸⁻¹² concerning the potential substitution of conventional vaccines by anti-idiotypic antibodies, this strategy is only in its early stages¹³. In the context of schistosomiasis, idiotypic vaccines could be of particular use when relevant protective epitopes cannot easily be produced by the modern tools of molecular biology. Although the rat is a non-permissive host, there is now clear evidence¹⁴ that all the specific effector mechanisms of immunity described in this model also occur in human infection. The possibility of using such immunization procedures in humans remains unexplored and cannot be directly extrapolated from experimental infections. However, work in progress in our laboratory, indicating the existence of cross-reacting idiotypes in human schistosome infection, is encouraging.

We thank Claudine Colson for her help in the preparation of the manuscript. This work was supported by INSERM U167-CNRS 624 and the WHO-UNDP Special Program for Research and Training in Tropical Diseases.

Individual-specific 'fingerprints' of human DNA

A. J. Jeffreys*, V. Wilson* & S. L. Thein†

* Department of Genetics, University of Leicester, University Road, Leicester LE1 7RH, UK

† MRC Molecular Haematology Unit, Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Headington, Oxford OX3 9DU, UK

Simple tandem-repetitive regions of DNA (or 'minisatellites') which are dispersed in the human genome frequently show substantial length polymorphism arising from unequal exchanges which alter the number of short tandem repeats in a minisatellite¹⁻⁴. We have shown previously that the repeat elements in a subset of human minisatellites share a common 10-15-base-pair (bp) 'core' sequence which might act as a recombination signal in the generation of these hypervariable regions⁵. A hybridization probe consisting of the core repeated in tandem can detect many highly polymorphic minisatellites simultaneously to provide a set of genetic markers of general use in human linkage analysis⁵. We now show that other variant (core)_n probes can detect additional sets of hypervariable minisatellites to produce somatically stable DNA 'fingerprints' which are completely specific to an individual (or to his or her identical twin) and can be applied directly to problems of human identification, including parenthood testing.

Three human minisatellites, termed 33.5, 33.6 and 33.15, each comprised of tandem repeats of various versions of the core sequence, have been cloned previously and characterized⁵ (Fig.

Table 1 Similarities of DNA fingerprints between random pairs of individuals

Probe	DNA fragment size (kb)	No. of fragments per individual $\pm$ s.d.	Probability x that fragment in A is present in B	Maximum mean allelic frequency/homozygosity
33.6	10-20	2.8 $\pm$ 1.0	0.11	0.06
	6-10	5.1 $\pm$ 1.3	0.18	0.09
	4-6	5.9 $\pm$ 1.6	0.28	0.14
33.15	10-20	2.9 $\pm$ 1.0	0.08	0.04
	6-10	5.1 $\pm$ 1.1	0.20	0.10
	4-6	6.7 $\pm$ 1.2	0.27	0.14

Samples (8 μ g) of blood DNA⁶ taken from a random sample of 20 unrelated British caucasians were digested with *Hinf*I and Southern blot hybridized with minisatellite probes 33.6 or 33.15 as described in Fig. 1 legend. Each DNA fingerprint (individual A) was compared with the pattern in the adjacent gel track (individual B), and the number of bands in A which were clearly absent from B, plus those which had a co-migrating counterpart of roughly similar autoradiographic intensity in B, were scored. The data shown are averages for all pairwise comparisons. A small proportion (~6%) of additional weakly hybridizing fragments in A were matched by strongly hybridizing fragments in B, and because in such cases it was not possible to decide whether the band in A was also present in B, such fragments were ignored. If co-migrating bands in A and B are always identical alleles of the same minisatellite locus, then the probability x that an allele in A is also present in B is related to the frequency q of that allele by $x = 2q - q^2$. As the allele frequency is low, then $q^2 \ll q$ and therefore the mean probability $\hat{x}$ is approximately related to the mean allele frequency $\hat{q}$ by $\hat{x} \approx 2\hat{q}$. Furthermore, assuming that there is little variance in q between alleles, then the number of alleles $n \approx 1/\hat{q}$ and the mean homozygosity is therefore approximately given by $\sum q_i^2 \approx n\hat{q}^2 = \hat{q}$. In practice, an (unknown) proportion of co-migrating bands in A and B will be derived by chance from different minisatellite loci, and thus the estimates of mean allele frequency and homozygosity are maximal and depend on the electrophoretic resolution of minisatellite fragments. Probability estimates: the mean probability that all fragments detected by probe 33.15 in individual A are also present in B is $0.08^{29} \times 0.20^{51} \times 0.27^{67} = 3 \times 10^{-11}$.

Fig. 1 Hypervariable fingerprints of human DNA. DNA samples prepared from three individual placentae (1-3) were digested with *HinfI* and/or *Sau3A* and Southern blot hybridized with ^{32} P-labelled single-stranded DNA probes prepared from M13 recombinants 33.5, 33.6 or 33.15, each of which contains a human minisatellite consisting of tandem repeats of closely related variants of the consensus sequences shown; the repeat unit in 33.6 is in turn a diverged trimer⁵. Each probe produces a different fragment pattern whose complexity is largely independent of the tetranucleotide restriction endonuclease used. Resolution of polymorphic fragments less than 4 kb long is improved in double digests with *HinfI* plus *Sau3A*, due to the elimination of background hybridization caused presumably by relatively diverged and invariant *HinfI* minisatellite fragments⁵ which have accumulated *Sau3A* cleavage sites within one or more repeat units. In double digests, the number of resolvable polymorphic fragments detected by probe 33.15 can be increased from ~15 to ~23 per individual, at the expense of losing ~20% of long single-digest minisatellite fragments which presumably contain a *Sau3A* cleavage site in most or all repeat units.

Methods. DNA was isolated from fresh human placenta as described elsewhere⁶. Samples (8 μ g) of DNA were digested with *HinfI* and/or *Sau3A*, in the presence of 4 mM spermidine trichloride to aid complete digestion, recovered after phenol extraction by ethanol precipitation, and electrophoresed through a 20-cm long 0.6% agarose gel at 30 V for ~24 h, until all DNA fragments <1.5 kb long had electrophoresed off the gel. DNA was then transferred by blotting to a Sartorius nitrocellulose filter⁷. High specific activity ($>10^9$ c.p.m. ^{32} P per μ g DNA) single-stranded M13 probes were prepared as described previously⁵. The precise probes used were: 33.5, a 220-nucleotide *HaeIII* fragment containing the minisatellite plus 60 nucleotides of flanking human DNA, subcloned into the *SmaI* site of M13mp8 (ref. 8); 33.6, a 720-nucleotide *HaeIII* fragment containing the minisatellite plus 50 nucleotides of flanking human DNA subcloned into the *SmaI* site of M13mp8; 33.15, a 592-nucleotide *PstI/AhaIII* fragment containing the minisatellite plus 128 nucleotides of flanking human DNA subcloned into M13mp19 DNA digested with *PstI* plus *SmaI*. Southern blot hybridization and washing were performed in $1\times$ SSC at 65°C as described previously⁵. Filters were autoradiographed at room temperature without an intensifier screen for 4 days.

1). Probe 33.15 has been shown to hybridize to multiple hypervariable fragments in *HinfI* digests of human DNA⁵. Probes 33.5 and 33.6 also detect a complex set of hypervariable regions in human DNA (Fig. 1). Probes 33.5 and 33.15 contain repeats of a similar version of the complete core sequence and consequently produce similar, but not identical, DNA fingerprints. In contrast, probe 33.6 is comprised of a shortened derivative of the core and hybridizes to a largely novel set of hypervariable fragments. Probe 33.15 detects ~15 resolvable hypervariable fragments per individual in the 4–20-kilobase size range, whereas probe 33.6 detects ~11 additional fragments of this size which are not detected by probe 33.15. Probe 33.5 hybridizes on average to about two further large fragments not detected by probes 33.6 or 33.15.

The DNA fingerprint pattern for the longest hypervariable fragments is largely independent of the 4-bp recognition restriction endonuclease used (Fig. 1). This strongly suggests that these large fragments are not derived from longer minisatellites, but that each contains a complete long homogeneous minisatellite devoid of restriction endonuclease cleavage sites and flanked by human DNA containing the normal high density of 4-bp cleavage sites. This is in agreement with previous data showing that most of these large minisatellite fragments are unlinked and segregate independently in pedigrees⁵.

To determine the variability of DNA fingerprints, DNA samples from a panel of 20 unrelated British caucasians were digested with *HinfI* and fingerprinted using probes 33.6 and 33.15 (Table 1). Pairwise comparisons of the DNA fingerprints showed that the minisatellite patterns were highly specific to an individual, and that few fragments are shared between two randomly selected individuals. The probability of shared bands increases for smaller minisatellite fragments, probably resulting from lower genetic variability (higher allele frequencies) of these loci⁵ combined with the fortuitous co-migration of unrelated

minisatellite fragments. From the degree of band sharing, one can obtain maximal approximate estimates of mean allele frequency and homozygosity (Table 1). For the longest minisatellite fragments in particular, the mean allele frequency is very low (<0.04) and the mean heterozygosity rises to $>96\%$. This is consistent with previous pedigree analysis which has shown that most of these large hypervariable DNA fragments are present in the heterozygous state⁵.

The data in Table 1 allow us to estimate the individual specificity of a DNA fingerprint. For probe 33.15, the probability that all 15 resolved fragments in the 4–20-kb size range in an average individual A are also present in a second unrelated individual B is 3×10^{-11} (see Table 1 for details of probability estimates); the probability that the fingerprints of A and B are identical, that is, that all fragments less than 4 kb also match and that B does not possess any additional 4–20-kb fragments, is therefore $\ll 3\times 10^{-11}$. Similarly, the probability that A and B have identical fingerprints for both probes 33.15 and 33.6 is $\ll 5\times 10^{-19}$. If individuals A and B are related, the chance of fingerprint identity is increased, to a maximum for parents/offspring and sibs. For nonconsanguineous marriages, as the heterozygosity for each fragment is very high, the probability that a hypervariable fragment in sib A is present in sib B is $\sim 1/2$, and thus the probability that all 15 resolved bands detected by probe 33.15 in sib A are present in sib B is $\sim 2^{-15} = 3\times 10^{-5}$ ($\sim 10^{-8}$ for both probes 33.15 and 33.6). These DNA fingerprints are therefore almost totally individual-specific, even within a single family (except for identical twins, see below).

The DNA fingerprints obtained using these core minisatellite probes are reproducible and are suitable for individual identification. In addition, sufficient DNA (0.5–5 μ g) can be isolated rapidly from a single drop of human blood for DNA fingerprinting. This is illustrated in Fig. 2, in which DNA fingerprints were produced from a randomized panel of individuals, including

Fig. 2 Individual identification using DNA fingerprints from small samples of blood. DNA was prepared by a rapid procedure using one or two drops of blood from a panel of 11 individuals and digested with *Hinf*I; DNA fingerprints were prepared as described in Fig. 1 legend, using 33.15 as a probe. The panel consisted of nine unrelated individuals, two of whom had been previously DNA fingerprinted, plus two sisters. The autoradiograph was inspected by a colleague who was unaware of the order of samples on the autoradiograph. He correctly identified the two previously fingerprinted individuals on the basis of pattern identity, as well as identifying the two sisters, who have several bands in common (tracks S). He also correctly deduced the fact that duplicate samples had been taken from another individual (tracks D).

Methods. One or two drops (30–100 µl) of blood were collected from a fingerprick into a 1 ml 1×SSC in an Eppendorf centrifuge tube. Cells were pelleted in an Eppendorf microfuge for 1 min, haemolysed by rapid suspension in 1 ml water and immediately made isotonic by the addition of 0.25 ml 5×SSC. White blood cells, nuclei and red cell ghosts were pelleted by centrifugation for 3 min, resuspended in 0.2 ml 0.2 M Na-acetate pH 5.6 and lysed by the addition of SDS to 1%. The lysate was extracted twice with phenol/chloroform and DNA collected by two rounds of ethanol precipitation at room temperature. DNA was dissolved in 20 µl water and digested with *Hinf*I in the presence of 4 mM spermidine trichloride at 37°C for 1 h. Electrophoresis and hybridization were performed as described for Fig. 1.

two people whose DNA had been fingerprinted previously, and two sisters. The two previously characterized individuals could be readily and unambiguously identified on the basis of DNA fingerprint comparisons, as could the two sisters, who have a substantial number of minisatellite fragments in common.

We have shown previously that these hypervariable minisatellite fragments are stably inherited in a mendelian fashion, and that the mutation rate to a new length allele is low (of the order of 0.001–0.004 per locus per gamete for the longest minisatellite fragments)⁵. Several experiments show that these DNA fingerprints are also somatically stable, an essential prerequisite for identification purposes (Fig. 3). Thus, the DNA fingerprints for sperm and blood DNA are indistinguishable, as are the patterns of monozygous twins. Furthermore, the patterns appear to be stably maintained in cultured cells, as shown by comparing the DNA fingerprints of blood DNA with DNA isolated from Epstein-Barr virus-transformed lymphoblastoid cell lines derived from the same individual.

The DNA fingerprints produced by minisatellite probes 33.6 and 33.15 are therefore sufficiently stable and individual-specific for use in human identification in, for example, forensic medicine, and could be used for the routine identification and authentication of human cell lines in culture. They also provide a reliable method for paternity testing (see Fig. 3). Approximately half of the polymorphic minisatellite fragments in an offspring are derived from the father, and these paternal frag-

Fig. 3 Somatic stability of DNA fingerprints and their use in paternity testing. Patterns of hypervariable DNA fragments are compared between blood (B) and sperm DNA (S) of individual 4, and between blood DNA (B) and DNA isolated from transformed lymphoblastoid cell lines (L) derived from related individuals 5–7 (6 is the daughter and 7 is the maternal aunt of woman 5; the kinship is evident in the number of fragments shared by these individuals). DNA fingerprints are also shown for blood DNA from identical twins (9, 10) and are compared with their mother (8), father (11) and two unrelated men (12, 13). Resolved paternal DNA fragments in the twins (arrows) were identified by eliminating maternal bands, and are all present in the father but not in individuals 12 or 13.

Methods. Lymphoblastoid cell lines transformed by Epstein-Barr virus⁹ and stored in liquid nitrogen were re-established in liquid culture after 2 yr. These cultured lymphocytes were washed twice in normal saline; DNA from the lymphocyte pellet and from white blood cells was prepared as described elsewhere⁶. Sperm DNA was prepared similarly, except that sperm collected from semen were treated with 1 M 2-mercaptoethanol for 5 min at room temperature before lysis with SDS. DNA fingerprints were prepared as described for Fig. 1, using 5-µg samples of DNA digested with *Hinf*I and hybridized with probe 33.6 (a) or 33.15 (b).

ments can be identified by comparison of the mother's and offspring's DNA fingerprints. All of these paternal fragments must be present in the father (allowing for a possible rare new mutation). Because, in practice, probe 33.15 will detect approximately six resolved paternal fragments in the 4–20-kb range (Table 1, Fig. 3), we can use the data in Table 1 to estimate the probability that incorrect paternity will not be detected, that is, that the putative father will by chance possess all six paternal-specific DNA fragments. This probability is low ($\sim 5 \times 10^{-5}$) if the putative father is not related to the true father, but increases to $\sim 2^{-6} = \sim 0.016$ if they are closely related (brothers, father/son). If both probes 33.6 and 33.15 are used, these probabilities are reduced to $\sim 4 \times 10^{-8}$ and $\sim 8 \times 10^{-4}$, respectively, although the precise probabilities will depend on the exact resolution and complexity of the DNA fingerprint patterns obtained, and will be improved if additional paternal fragments <4 kb long can be identified (for example, by using double digests, Fig. 1). We conclude that in the vast majority of cases, the combined use of probes 33.6 and 33.15 will be sufficient to identify cases of incorrect parenthood. An interesting corollary is that these DNA fingerprints could be used with an equal level of reliability to establish true biological parentage.

This work is the subject of a UK patent application. Enquiries should be addressed to the NRDC. We thank John F. Y. Brookfield for helpful discussions, Dr R. S. Pereira for help and advice with lymphoblastoid cell lines, and Dr G. Corney and many

volunteers at Leicester for providing blood samples. A.J.J. is a Lister Institute Research Fellow, and this work was supported by a grant to A.J.J. and a Training Fellowship to S.L.T. from the MRC.

DNA restriction fragments associated with α_1 -antitrypsin indicate a single origin for deficiency allele *PI Z*

Diane Wilson Cox, Savio L. C. Woo* & Tammy Mansfield

Research Institute, Hospital for Sick Children, 555 University Avenue, Toronto, Canada M5G 1X8 and Departments of Paediatrics, Medical Genetics & Medical Biophysics, University of Toronto, Toronto, M5S 1A8, Canada

* Howard Hughes Medical Institute, Department of Cell Biology, Baylor College of Medicine, Houston, Texas 77030, USA

The α_1 -protease inhibitor, or α -antitrypsin (AAT), a major plasma inhibitor of leukocyte elastase and bacterial proteases, is encoded at the *PI* locus on chromosome 14 (14q24.3-q32.1)¹. A deficiency of AAT in individuals homozygous for the *PI Z* allele occurs in about 1 in 2,000-8,000 caucasians² and is associated with an increased risk of early adult onset emphysema³ and liver disease in childhood⁴. We have now used DNA polymorphisms associated with the AAT gene to investigate the origin of the *PI Z* allele. Using two genomic probes⁵ extending into the 5' and 3' flanking regions, respectively, we have identified eight polymorphic restriction sites. Extensive linkage disequilibrium occurs throughout the probed region with the *PI Z* allele, but not with normal *PI M* alleles. The *Z* allele occurs mainly with one haplotype, indicating a single, relatively recent, origin in caucasians.

Venous blood samples were collected in EDTA from 32 normal unrelated controls, 26 patients with AAT deficiency (*PI* type ZZ), and 15 pairs of parents and 16 sibs of patients with AAT deficiency. *PI* type ZZ patients included 12 adults with emphysema, 3 adults with liver disease, 9 children with liver disease and 2 healthy adults. Relatives of 16 normal controls were studied: members of 2 normal two-generation families with a total of 7 children, and 53 members of a three-generation family of a *PI* ZZ proband which included 12 unrelated spouses. The genetic type of AAT (*PI* type) was determined by isoelectric focusing of plasma in acrylamide gels, pH 3.5-6 (ref. 6). Blot hybridization of leukocyte DNA digested with specific enzymes

is described in Fig. 2 legend. The 5' probe (4.6 kilobases, kb) and 3' probe (6.5 kb) have been described elsewhere⁷ (Fig. 1), both having been subcloned from phage clone α AT35⁵.

Of 10 restriction enzymes tested with the 5' 4.6-kb probe, 3 showed restriction site polymorphisms; these were *Sst*I, *Msp*I and *Ava*II. For each enzyme, one or both of two possible restriction fragments were observed. When a particular restriction site was present (designated +), a shorter DNA fragment was observed than when the restriction site was absent (designated -). Family studies indicated that the pair of DNA fragments for each enzyme were alleles. Among 32 unrelated normal controls, the allele frequencies were as shown in Table 1. The 4.6-kb genomic probe has been completely sequenced⁸, so the positions of the restriction sites were identified. Fragments of the expected sizes were observed. The distances between restriction sites were 2 kb between *Sst*I and *Msp*I sites, and 0.2 kb between *Msp*I and *Ava*II sites.

A χ^2 analysis of 2x2 tables, or exact calculation of probabilities where required⁹, was used to examine the data for possible association between a specific allele at one site and a specific allele at each of the other two sites. No significant association between alleles was observed, indicating free recombination between the three restriction sites, with no evidence

Fig. 1 The α_1 -antitrypsin gene and adjacent flanking regions, described previously^{4,17}. Solid areas are coding regions, dots indicate untranslated regions, open areas are introns. Restriction sites for the enzymes *Eco*RI and *Bam*HI (B) are indicated. *, Polymorphic restriction sites for *Sst*I (S), *Msp*I (M) and *Ava*II (A). The two genomic probes used in this study are shown above the gene.

Fig. 2 Patterns of DNA fragments are shown for the three enzymes *Sst*I, *Msp*I and *Ava*II, using the 4.6-kb 5' probe. DNA extracted from leukocytes was completely digested with specific restriction enzymes according to conditions recommended by the manufacturer. Fragments were separated by size in 0.8% agarose gels. DNA fragments were transferred to Biodyne membranes (Pall). Probes were labelled with ³²P using a nick-translation kit (Amersham). After prehybridization, ³²P-labelled probe (3.0x10⁷ counts per filter) was hybridized overnight. Filters were rinsed twice in 2xSSC (SSC: 1.5x10⁻⁴ M NaCl, 1.5x10⁻⁵ M Na-citrate). Membranes were washed in 2xSSC at 60 °C for 45 min, then twice in 0.1% SDS in 0.1xSSC at 60 °C for 45 min, rinsed briefly in SSC, blotted, then exposed to X-ray film for 2-3 days. Fragment sizes in kb are indicated on the left. Anode is at the bottom. Arrows mark the polymorphic fragments. From left to right, lanes show the following allele designations: +-, ++, --, --, ++, ++, +-; ++, +-, ++, --.

Table 1 Allele frequencies for 5' DNA polymorphisms (4.6-kb probe)

Restriction enzyme	Alleles (kb)	Allele frequency +	Allele frequency -	PIC*
<i>Sst</i> I	1.8, 1.9	0.649	0.351	0.35
<i>Msp</i> I	0.95, 0.98	0.506	0.494	0.38
<i>Ava</i> II	0.9, 1.1	0.636	0.364	0.36

* Polymorphism information content, calculated according to the formula of Botstein *et al.*²¹, expressing the extent of variability at each locus.

Fig. 3 DNA fragments observed using restriction enzyme *Ava*II and the 6.5-kb probe. Sizes of fragments are indicated in kb, anode is at the bottom. The seven polymorphic fragments are numbered on the left. There are also three strong bands present between polymorphic bands 1 and 2 which appear to be constant in all samples observed to date. The *Ava*II DNA phenotypes observed in each lane are as follows: (1) 11336677; (2) 11336655; (3) 10334677; (4) 10334657; (5) 11236657; (6) 11336657. The arrow in lane 1 shows the unique region of the pattern associated with PI type ZZ.

of linkage disequilibrium between them in normal individuals, despite the close proximity of sites. The specific combination of the three restriction sites (DNA haplotype) was determined by segregation within families. Forty-seven non-Z haplotypes (M of various subtypes and S) could be determined from 16 normal controls and from 15 parents of PI ZZ children using only the non-Z haplotype. The specific haplotypes found with each PI type are shown in Table 2. The expected haplotypes for all non-Z PI types were calculated on the assumption that each restriction site polymorphism segregates independently, so that the probability of a particular haplotype occurring is the product of each of the component allele frequencies. There is no significant difference between observed and expected frequencies ($\chi^2 = 10.7$; d.f. = 7) for the data available (Table 2), although the $-++$ and $-+-$ categories may be decreased in larger series. Again, the conclusion is that there has been considerable recombination between the three restriction sites, with no linkage disequilibrium for non-Z haplotypes. The DNA haplotypes found in combination with specific PI types are shown in Table 2. Further data will be required to determine whether there is linkage disequilibrium between each specific PI type and specific haplotypes, although our data suggest there is disequilibrium for PI variants M3 and S.

In contrast to the results for the normal non-Z PI types, among the 26 unrelated individuals with AAT deficiency (PI type ZZ), 25 were homozygous for the haplotype *Sst*I $-$, *Msp*I $+$, *Ava*II $+$. The haplotype $-++$ therefore occurred with 51 of 52 PI Z alleles. One PI Z allele was associated with the 5' DNA haplotype $+++$, indicating a crossover event between the *Sst*I and *Msp*I sites, or a mutation at the *Sst*I site. There is therefore a very high degree of linkage disequilibrium for the 5' restriction sites of PI Z alleles. This specific haplotype ($-++$) is found in association with 8 of 28 PI M1 alleles and 1 of 13 M2 alleles, suggesting that the PI Z allele has been derived from the PI M1 allele. The amino-acid sequence of the Z AAT product differs in one position from that of M, subtype undefined: at position 342 in exon V, glutamine in M is changed to lysine in Z^{10,11}.

Further polymorphisms were found using the 3' 6.5-kb probe and the restriction enzyme *Ava*II. The pattern of DNA fragments

included at least seven polymorphic fragments and three constant fragments, ranging in size from 0.48 to 2.7 kb (Fig. 3). Because sequencing is incomplete for the region of the 6.5-kb probe, not all specific sites have been identified, so fragments have been numbered. The polymorphic band 1 (2.7 kb) was either present or absent, indicated as alternate alleles 0 or 1, with frequencies of 0.36 and 0.64, respectively. The fragment labelled 2 (1.15 kb) (Fig. 3, lane 5) represents a rare allele, frequency 0.02. Bands 4 (0.72 kb) and 6 (0.64 kb) are alleles, frequencies 0.30 and 0.70, respectively. At least one constant fragment is also present in position 6. Alleles represented by bands 5 (0.68 kb) and 7 (0.48 kb) have frequencies of 0.07 and 0.30, respectively. Fragment 7 transfers inefficiently and can usually be seen clearly only when present in the homozygous state. The proposed interpretation of alleles is supported by family studies.

The phenotype observed in lane 1 of Fig. 3, with both bands 4 and 5 absent, was not observed in 32 normal control individuals. However, this band pattern was observed in all of 26 individuals of PI type ZZ. The particular combination of *Ava*II DNA fragments can be stated as a haplotype. PI type ZZ individuals are therefore homozygous for the haplotype 1367. Of the 47 non-Z haplotypes determined by family studies, none has the 1367 haplotype. The most common *Ava*II haplotype is 1365, found with 27 of 47 non-Z alleles (11/28 M1, 10/13 M2, 4/4 M3 and 2/2 S). This haplotype would require only one mutation to produce an *Ava*II restriction site to convert fragment 5 to fragment 7. About 75% of the region of the probe has been sequenced⁸ and fragments of the sizes of polymorphic bands 2, 3, 4, 5, 6 and 7 are located within the AAT gene. Two additional restriction site polymorphisms, one within the gene and one in the 3' flanking region, were observed using the 3' probe and the restriction enzyme *Taq*I (data not shown). The polymorphic *Taq*I sites are identical for 51 of 52 Z haplotypes; the exception involves a *Taq*I site 3' to the AAT gene.

The finding of a single unique DNA haplotype for most (96%) PI Z alleles is exceptional for diseases studied to date. The first association of a DNA restriction fragment polymorphism with a disease was described for sickle-cell anaemia¹². Multiple restriction sites associated with the sickle-cell haemoglobin gene indicate three independent origins in Africa¹³. For thalassaemia, a specific restriction fragment haplotype is generally associated with a specific mutant gene and haplotypes tend to be characteristic for defined ethnic groups¹⁴. In contrast, for AAT, the mutant gene is almost always associated with a single haplotype, indicating a single origin for the PI Z allele. While most patients in the present study are of British origin, others are Ukrainian, German, Dutch and French. Many different population groups have now been surveyed², and have shown that the PI Z allele is limited to caucasians and is not found in oriental or black population groups, except where it can be explained by racial admixture. Also, there is a suggestion of a decreasing gene frequency from north to south in European populations. The

Table 2 DNA restriction fragment haplotypes (5' 4.6-kb probe) associated with specific PI types

Haplotype			Total non-Z		PI type*				
<i>Sst</i> I	<i>Msp</i> I	<i>Ava</i> II	Observed	Expected	M1	M2	M3	S	Z

Totals			47	47	28	13	4	2	52

* Controls were selected before PI typing; frequencies of PI types therefore reflect population frequencies²².

PI Z allele has certainly arisen since the divergence of the races, and probably much more recently. The number of generations which have elapsed since the origin of the *PI Z* mutation can be estimated, assuming that meiotic crossing-over is a random event (which is not strictly true) and that on average there is roughly one meiotic crossover per 10^8 base pairs per generation¹⁵. As the crossover frequency is 1 in 52, and the estimated distance between the most 5' restriction site (*Sst*I) and the most 3' *Ava*II polymorphic site is approximately 9×10^3 base pairs, it can be calculated that 216 generations, or 6,480 yr, would be required to generate 1.9% crossovers. Because no crossovers have occurred in the 7-kb distance between the 5' *Msp*I site and the most 3' *Ava*II site, the number of generations may be considerably less. The lack of linkage disequilibrium between the three 5' polymorphic restriction sites suggests an ancient origin for the polymorphisms, or a region of high recombination. Differential rates of recombination have been shown within the β -globin¹⁶ and immunoglobulin¹⁷ clusters. After the single

origin in a northern caucasian race, selective forces may have increased the frequency of the *PI Z* allele (see ref. 2 for a review). Such selective forces may be direct; AAT may be directly involved in the fertilization process and the decreased concentration in *PI Z* heterozygotes could enhance fertility^{18,19}.

In addition to providing information on the origin of the *PI Z* allele, the studies reported here show that various clinical manifestations of the disease are associated with only one mutant allele. Furthermore, the unique *Ava*II haplotype provides a basis for prenatal diagnosis²⁰.

We thank Drs Vincent Kidd and Torben Bech-Hansen, respectively, for subcloning the probes and assisting in probe preparation; Diane Wills for PI typing and DNA extraction; Patricia Zavitz for obtaining blood samples; and Beverly Bessey for typing the manuscript. Many physicians have provided access to their patients and their contribution is appreciated. This study was supported in part by grants from the MRC of Canada (MA5426) to D.W.C. and from NIH (HL27509) to S.L.C.W.

Spontaneous excision of a large composite transposable element of *Drosophila melanogaster*

W. Chia*, S. McGill, R. Karp*, D. Gubb & M. Ashburner

Department of Genetics, University of Cambridge, Cambridge CB2 3EH, UK

The *TE1* family of transposable elements (TEs) of *Drosophila* consists of unusually large transposons, cytologically visible in larval polytene chromosomes as one or more bands¹⁻³. They are composite elements, as their termini consist of foldback (FB) sequences which are themselves transposable⁴⁻⁶. The location of FB elements at the termini of transposable elements suggests that these sequences have a direct role in the genetic instability of TEs. To investigate the structural and phenotypic consequence of TE excision, we have cloned genomic DNA required for the expression of the *no-ocelli* (*noc*) gene of *Drosophila*; this gene has been mutated by the insertion of *TE146*, a member of the *TE1* family carrying six polytene chromosome bands including functional copies of the *white* (*w*⁺) and *rough* (*rst*⁺) genes. As reported here, our experiments indicate that the spontaneous excision of *TE146*, which results in the loss of the *w*⁺ and *rst*⁺ markers, can occur either as a single-step event or following a partial internal deletion. In either case, the end product is an imprecise excision in which a residual portion of the element, varying in size from 3 to 10 kilobases (kb), is left at the insertion site. These residual sequences share homology with the FB family. Furthermore, despite their imprecise nature, all these spontaneous excisions restore a wild-type *noc*⁺ phenotype.

The first transposable element identified arose from the spontaneous transposition of two adjacent genes, *w*⁺ and *rst*⁺, from

Fig. 1 *a*, Polytene chromosomes of a *TE146/+* heterozygote, showing the six bands of the TE inserted near bands 35B1.2. Arrowheads indicate the cytological limits of *TE146*. *b*, Polytene chromosomes of homozygous *TE146* hybridized with a nick-translated probe prepared from a clone (M365; ref. 6) including sequences from the *w*⁺ gene. There are two bands of homology to the probe within the TE and one at 3C1, the normal locus of *w*⁺. Arrowheads indicate sites of hybridization within *TE146*. *c*, Polytene chromosomes of homozygous *TE146* hybridized with a nick-translated probe prepared from a clone (FB8) including sequences of the repetitive FB element^{4,5}. Note that there are at least two discrete sites of hybridization within the TE (arrows).

their normal location on the X chromosome to chromosome arm 2R. The element (*TE1*) resulting from this original transposition is mobile and its derivatives have been mapped to over 150 cytological locations throughout the *Drosophila* genome².

Transposable elements can induce mutations in genes that lie at, or near, their insertion sites; for some, but not all, of these TE-induced mutations, the subsequent loss of the element leads to a restoration of the wild-type phenotype². To understand this observation, and to clarify the role of FB sequences in TE instability, we examined the structural consequences of TE loss. For this purpose, *TE146*, a member of the *TE1* family which

* Present addresses: Department of Biochemistry, University of Bristol, Bristol BS8 1TD, UK (W.C.); Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138, USA (R.K.).

Fig. 2 a, Polytene chromosomes of TE146/CyO hybridized with a genomic clone, λ ob 9.04, that crosses the site of insertion of the TE. The single site of hybridization to the wild-type homologue (open arrowhead) is split into two by the insertion of the TE (solid arrowheads). Cy indicates the left breakpoint of the *In(2L)Cy* component of CyO. **b**, Restriction enzyme site map of a 25-kb genomic region of *Iss2* (the wild-type strain carrying the chromosome into which the TE had integrated to form TE146) which spans the TE insertion site. Recombinant clones containing the two 12-kb genomic *EcoRI* fragments which comprise this region were isolated from an EMBL-4 library constructed from *Iss2* DNA by virtue of homology with the insert of λ ob 9.04 (see text). The *EcoRI* fragments were subsequently subcloned into pUC9. The extents of λ ob 9.04 and of subclones which were used as probes are shown as solid lines above the restriction map. The TE is represented by the large triangle. Restriction enzyme sites internal to the element were determined from Southern transfer experiments. The site of insertion lies within the 700-bp *HindIII/SalI* fragment and is less than 50 bp from the *SalI* site, the *SstI* site located just within the proximal terminus of the TE being less than 50 bp from this *SalI* site. For this reason, the 700-bp *HindIII/SalI* fragment (probe 2) will only detect fragments spanning the distal junction of the element. R, *EcoRI*; Xh, *XhoI*; Ss, *SstI*; B, *BamHI*; Sa, *SalI*; H, *HindIII*; Xb, *XbaI*. **c**, *Iss2* and TE146 genomic DNA was digested with *HindIII/SalI*, fractionated on a 0.8% agarose gel and transferred to nitrocellulose membrane. The filter was hybridized to probe 4, ^{32} P-labelled by nick-translation, then washed and autoradiographed. Lane 1, *Iss2*; lane 2, TE146. Label was removed from the filter with two washes in 0.1 M NaOH at room temperature then it was re-hybridized to probe 2, washed and autoradiographed. Lane 3, *Iss2*; lane 4, TE146.

Fig. 3 Restriction enzyme-digested DNA was fractionated on 0.8% (a, b) and 0.6% (c) agarose gels and transferred to nitrocellulose membrane. The filters were hybridized to the probes indicated below, then washed and autoradiographed. Where the same filter was re-used for different probes, label hybridized to the filter was removed by washing with 0.1 M NaOH before hybridization with the subsequent probe. **a**, All samples were digested with *EcoRI*. Lane 1, *Iss2*; lane 2, TE146; lanes 3–15, different strains carrying independent spontaneous excision chromosomes (hybridized with probe 1). **b**, The same filter used for **a** was hybridized to probe 2; an identical result was seen when probe 3 was used. **c**, All samples were digested with *EcoRI/HindIII*. Lanes 1–8, different strains carrying independent spontaneous excision chromosomes; lane 9, *Iss2*. Markers used are *HindIII*-digested λ DNA. Identical results were obtained with either probe 1 or 2. The faint 4-kb band in lane 9 results from partial digestion with *HindIII*. The lanes in **c** and **a** which correspond to the same excision derivatives are as follows: (tracks in **c** are indicated first) 1 = 2, 2 = 4, 3 = 5, 4 = 9, 5 = 8, 6 = 12, 7 = 15; track 8 in **c** is not represented in **a**.

contains two copies of w^+ , was chosen because chromosomes from which this element had been spontaneously lost were available, as was a large region flanking its insertion site. In larval salivary gland chromosomes, this element contains six chromosomal bands, equivalent to several hundreds of kilobases of DNA (see Fig. 1a). Like other members of the TE family, TE146 shares homology with the cloned *w* and *FB* sequences (Fig. 1b, c). Both copies of the *w* genes carried by TE146 are functional, and spontaneous excision events have previously been isolated by selecting for the absence of w^+ (ref. 7). The site of insertion is associated with *noc*, a gene that is two complementation groups distal to the alcohol dehydrogenase (*Adh*) gene on chromosome arm 2L⁸. Flies carrying homozygous deletions of the *noc* gene are viable, but lack ocelli and associated bristles. TE146 abolishes *noc*⁺ function, so it is associated with a strong recessive *noc* mutation.

The insertion site was sufficiently close to *Adh* to be cloned by chromosomal walking⁹. Using the cloned *Adh* gene as a starting point¹⁰, overlapping DNA fragments were isolated from a wild-type Canton-S library¹¹ until the insertion site was reached. That DNA spanning the insertion site of TE146 had been obtained was shown by *in situ* hybridization to larval salivary gland chromosomes. The phage clone λ ob 9.04, containing DNA located roughly 100 kb distal to *Adh*, hybridizes with both sides of the element (Fig. 2a); it therefore contains DNA sequences spanning the insertion site. Using as a probe the *Drosophila* DNA contained within λ ob 9.04, we isolated a 25-kb segment of DNA from a phage bank constructed from the genomic DNA of the strain of flies carrying the chromosome into which the TE had integrated to form TE146. The restriction map of this DNA, and Southern transfer experiments which localize the insertion site to a 700-base pair (bp) *SalI/HindIII* fragment, are shown in Fig. 2b, c.

We have analysed eight independent spontaneous excision chromosomes derived from TE146 which, in addition to having lost the w^+ markers, are cytologically wild type at the insertion site. Southern filters of gel-fractionated DNA digests from these strains were prepared, and the filters were hybridized to two different probes, one with sequences adjacent and distal to, the other with sequences adjacent and proximal to, the insertion

Fig. 4 *In situ* hybridization of the FB8 probe to two different chromosomes that have spontaneously lost TE146 (see Fig. 1c). The arrow indicates FB homology at bands 35B1.2. Cy indicates the left break of *In(2L)Cy*: a, TE146(Z)SW22/CyO; b, TE146(Z)SW13/CyO.

site (see Fig. 2 legend). Figure 3a, b shows the resulting autoradiograms. In TE146 the distal probe hybridizes to a 20-kb *Eco*RI band which spans the distal junction of the element and adjacent chromosomal DNA, whereas the proximal probe hybridizes to a 7.5-kb band corresponding to the proximal junction. By contrast, each of the lanes containing spontaneous excision chromosome samples contains a single band which appears to be homologous to both probes; this is clearly one band which hybridizes to both probes, and not two different bands of the same size, because consistent results were obtained when this experiment was repeated after the DNA had been cut with different restriction enzymes (data not shown). As homology to both the 700-bp proximal and distal probes is observed, these excision events have not deleted more than 700 bp of chromosomal DNA sequences immediately flanking either side of the insertion site. The simplest interpretation of the data is that these events resulted from the deletion of most, but not all, of the several hundred kilobases of DNA sequence associated with the element. The amount of TE DNA remaining in these chromosomes can be determined from the increased sizes of the wild-type 1.4-kb *Eco*RI/*Hind*III fragment spanning the transposable element insertion site. The fragment varies between 3 and 10 kb in the excision chromosomes examined (Fig. 3c). *In situ* hybridization experiments indicate that the remaining DNA shares homology with cloned FB sequences (see Fig. 4).

FB elements are implicated in mediating these excision events because of their location at the termini of elements belonging to the TE1 family³. The terminal structure of FB elements, combining short tandem repeats within large inverted repeats, could promote homologous pairing, in and out of register, between the inverted repeats⁴. Where two FB elements flank an intermediate sequence, as in members of the TE1 family, pairing and recombination between two repeats (one from each FB element) in the same orientation will result in the loss of the intermediate sequence and the retention of a variable portion of the FB sequences. The loss of DNA flanked by FB elements has been shown previously for two *w* mutations, white-crimson (*w^c*) and Dominant zeste-like (*w^{DZL}*)^{12,13}. There are, however, two differences between the loss of TE146 from *noc* and the losses of the FB-associated insertions from *w*: (1) losses of TE146 are selected on the basis of a function carried by the element itself, rather than a function which is affected by the position of the element; (2) the DNA separating the FB elements is <14 kb for *w^c* and *w^{DZL}*, whereas we estimate a minimum of 200 kb for TE146.

While the events described above, in which essentially all of the TE is lost in a single generation, occur relatively infrequently ($\sim 5 \times 10^{-5}$) (ref. 7), partial deletions of the element, which result in the loss of only one copy of the *w⁺* gene, can occur at much higher frequencies ($\sim 5 \times 10^{-4}$). These partially deleted chromosomes retain several polytene bands associated with the transposable element, and may result from exchange between a

terminal FB element and one internal to the TE, separating its two *w⁺* genes. These partial deletions do not revert *noc*, but subsequent loss of the remaining bands can restore a wild-type *noc⁺* phenotype (D.G. *et al.*, unpublished data). Such losses of TE146 in two stages, via the partial deletion intermediate, result in chromosomes which are indistinguishable from the one-step excision events already described; they retain <10 kb of FB-homologous sequences at the insertion site. The length of the insertion varies among different independently derived losses (data not shown).

Paro *et al.*¹⁴ have suggested that the presence of FB elements at the termini of the TE1 family may be the cause of their genetic instability. The results presented here indicate that the excision of the six intervening chromosomal bands of TE146 from their site of insertion could result from recombination between the terminal FB elements of the transposable element. The imprecise nature of these excisions provides an explanation for the lack of correlation between excision and reversion for most of the mutations induced by this family of elements^{1,2,15}. In the case of TE146, however, all the imprecise excision events, regardless of their mode of origin, restore a wild-type *noc⁺* phenotype. It would be difficult to rationalize this observation if TE146 had disrupted *noc* function by inserting into a coding portion of the gene. A possible explanation of the reversions is that the insertion of several hundred kilobases of DNA in close proximity to *noc* can disrupt its expression by virtue of a position effect. For example, the TE could alter the local chromatin structure and thereby affect *noc* expression. In this case, excision of the element, despite being imprecise, could restore normal expression by removing most of the material responsible for the structural alteration. A similar position effect observed for the *w^{DZL}* mutation is also removed by the deletion of DNA sequences between two FB elements.

Identification of myosin heavy chain in *Saccharomyces cerevisiae*

F. Z. Watts*, D. M. Miller† & E. Orr*

† MRC Laboratory of Molecular Biology, University Postgraduate Medical School, Hills Road, Cambridge CB2 2QH, UK

Motility in biological systems is expressed in a variety of ways, such as cytoplasmic streaming, cell shaping, nuclear migration and muscle contraction. These functions are thought to be mediated by structural proteins, for example, myosin, actin and tubulin (see ref. 1 for review). The involvement of myosin in muscle contraction is well documented and this protein is implicated in generating the cleavage forces during cytokinesis in some non-muscle cells².

Here, we report the isolation of a protein similar to myosin as judged by its biochemical and immunological properties, from the yeast *Saccharomyces cerevisiae*. Parts of the protein have been conserved through evolution at the protein and DNA sequence levels. The presence of this protein in the region bordering mother cell and bud, as revealed by immunofluorescence, suggests that it is involved in cell division.

In an attempt to isolate novobiocin binding proteins from yeast, we applied total cell extract to a novobiocin-Sepharose column³ and eluted the bound proteins with ATP, urea or increasing salt concentrations. Under these experimental conditions, several proteins were eluted in 1 M KCl or 5 M urea (data not shown). Among these were two proteins of relative molecular mass (M_r) $200,000 \pm 5\%$ present in both fractions. The high M_r of these proteins, combined with the fact that novobiocin inhibits the ATPase activity of bacterial topoisomerase type II through competition with ATP³, led us to examine whether one of these proteins could be a myosin heavy chain, which is known to contain an ATPase activity.

We first used polyclonal⁴ and monoclonal⁵ antibodies raised against nematode muscle myosin, in the Western blot technique⁶. The polyclonal IgG fraction recognizes the smaller of the two high M_r proteins (Fig. 1a, lanes 1, 3). Two monoclonal antibodies (out of a set of 22) raised against nematode myosin interact with the same yeast protein (Fig. 1a, lane 4), supporting this result. One of these antibodies (28.2) interacts with a moderately conserved region of the S2 proteolytic fragment of the nematode myosin heavy-chain isoform encoded by the *unc-54* gene⁵.

Several biochemical criteria have been proposed by Pollard⁷ and others to ensure a positive identification of myosin. The most important of these are its ability to form a complex with actin and its ATPase activity, sometimes stimulated by actin but always dependent on either Mg^{2+} or Ca^{2+} ions. The Ca^{2+} -dependent activity is especially striking, as other known cytoplasmic ATPases are almost exclusively Mg^{2+} -dependent and are usually inhibited by Ca^{2+} . Therefore, this activity is generally used to follow the purification of myosin from crude cell extracts. Table 1 shows that the ATPase activity of the 1 M KCl fraction eluted from the novobiocin-Sepharose column is actin activated (using purified rabbit actin) and is either Mg^{2+} or Ca^{2+} dependent.

To discover whether the putative myosin can form a complex with actin, we isolated actomyosin complexes under conditions similar to those described by Pollard⁷. Yeast spheroplasts were lysed in 10 mM Tris-HCl pH 7.9, 1 mM dithiothreitol; sodium pyrophosphate and sucrose were then added to final concentrations of 50 mM and 0.34 M, respectively, to ensure complete myosin solubilization. After a high-speed clearing spin (30,000 r.p.m.), the supernatant was dialysed against 10 mM sodium citrate, pH 6.5, to precipitate the actomyosin complex. The complex was collected by centrifugation at 30,000 r.p.m.; it is composed primarily of a M_r $200,000 \pm 5\%$ protein (Fig. 1b)

Table 1 ATPase activity of two crude myosin preparations from *S. cerevisiae*

	Novobiocin-Sepharose 1 M KCl fraction ($\mu\text{mol min}^{-1} \text{mg}^{-1}$)	Actomyosin complex ($\mu\text{mol min}^{-1} \text{mg}^{-1}$)
No additions	≥ 5	≥ 5
Mg^{2+}	150	220
Mg^{2+} /actin	250	220
Ca^{2+}	100	90
K^+ /EDTA	20	10

Assays of ATPase activity were performed in 25- μl aliquots containing 25 mM Tris HCl pH 7.5, 1 mM ATP and one of the following: (1) 5 mM $MgCl_2$; (2) 5 mM $MgCl_2$, 1 mg ml^{-1} rabbit actin; (3) 5 mM $CaCl_2$; (4) 20 mM KCl, 1 mM EDTA. The 1 M KCl fraction had been dialysed to remove the KCl. Inorganic phosphate was measured according to Lanzetta *et al.*¹³. The actin preparation did not contain any detectable ATPase activity.

Fig. 1 SDS-polyacrylamide gel electrophoresis and Western blot analysis of crude myosin preparations. *a*, Yeast spheroplasts, prepared using $50 \mu\text{g ml}^{-1}$ zymolyase in 1.2 M sorbitol were lysed in 50 mM Tris-HCl pH 7.9, 1 mM dithiothreitol, 50 mM KCl, 1 mM p-enylmethylsulphonyl fluoride. The resulting solution was subjected to centrifugation at 30,000 r.p.m. for 1 h. The supernatant was loaded onto a novobiocin-Sepharose column, which was then washed with 0.1 M KCl followed by 1 M KCl. Actomyosin complexes were precipitated using a modification of the method described by Pollard⁷. The 1 M KCl fraction (lanes 1-4) and actomyosin complex (lanes 5, 6) were analysed on a 5% SDS-polyacrylamide gel¹⁴ and either (lanes 1 and 5) stained with Coomassie brilliant blue or (lanes 2-4, 6) electroblotted to nitrocellulose⁶. The filter in lane 2 was stained for protein using India ink¹⁵. The filter in lane 3 was incubated with rabbit serum containing polyclonal antibodies against nematode myosin, followed by goat anti-rabbit IgG-peroxidase, while the filters in lanes 4 and 6 were incubated with a monoclonal antibody 28.2 against nematode myosin, followed by goat anti-mouse IgG-peroxidase. M_r marker (210 K) is rabbit myosin heavy chain. *b*, The actomyosin complex was analysed by SDS-polyacrylamide gel electrophoresis (12.5%). Lane 1, yeast actomyosin complex; lane 2, rabbit myosin heavy and light chains. M_r markers (from top to bottom) are rabbit myosin, *Escherichia coli* RNA polymerase, bovine serum albumin and pyruvate kinase.

and actin (as determined with yeast anti-actin IgG in an enzyme-linked immunosorbent assay and on a Western blot, data not shown). Western blot analysis showed that the monoclonal antibodies against nematode myosin reacted with the M_r 200,000 protein (Fig. 1a lanes 5, 6), strongly suggesting the presence of the myosin heavy chain in the complex. The ATPase activity of this complex is again either Mg^{2+} or Ca^{2+} -dependent (Table 1) but is not stimulated by actin, presumably because the latter is already present in sufficient quantities in the complex. In general, myosin is a hexameric molecule composed of two heavy chains and four light chains, each of $M_r \sim 20,000$. Thus far, we have not directly identified myosin light-chain molecules in yeast, although minor proteins of appropriate M_r are co-precipitated in the actomyosin complex (Fig. 1b).

The significance of the immunological data has been further investigated by Southern blot hybridization. A *Bam*HI fragment encoding the ATP-binding region of a nematode myosin heavy chain was hybridized to total genomic yeast DNA. This fragment spans a region that is conserved within the nematode myosin

Fig. 2 Southern blot analysis¹⁶ of *S. cerevisiae* genomic DNA with a nematode myosin DNA probe. Genomic DNA from A364A was digested with *EcoRI* (lane 1) or *BamHI* (lane 2), run on a 0.7% agarose gel and blotted to nitrocellulose. The filter was incubated with a nick-translated *BamHI* fragment, containing the region of a nematode myosin heavy-chain gene encoding the ATP-binding site⁸, in $2\times$ SSC (0.3 M NaCl, 30 mM sodium citrate) at 60 °C. Size markers are *HindIII* fragments of λ phage DNA.

heavy-chain gene family. Protein sequences in this fragment contain high homology to the ATP-binding region of myosin heavy chains from various organisms⁸. Figure 2 demonstrates that this probe hybridizes to a 1.2-kilobase (kb) *EcoRI* fragment and to a *BamHI* fragment of ~10 kb. A second DNA probe, carrying a less well-conserved sequence from the S2 region of the nematode *unc-54* myosin heavy-chain gene did not hybridize to yeast DNA (data not shown).

The detection of myosin heavy chain in yeast raises some interesting questions regarding its physiological roles in this and similar organisms. The possible role of myosin in non-muscle cells, as well as that of actin in yeast, have been suggested by their detection using *in situ* immunofluorescent techniques^{2,9,10}. Adopting a similar approach, we used either the nematode anti-myosin IgG or mouse serum containing anti-yeast myosin IgG (our unpublished results). Fixed cells were treated with anti-myosin IgG followed by a secondary IgG coupled to fluorescein isothiocyanate (FITC). Most of the fluorescence was localized at the junction between mother cells and buds (Fig. 3a). This fluorescent band becomes visible as soon as buds can be detected and disappears at the completion of cell division.

These data suggest that myosin is involved in the mechanism of budding, perhaps analogous to its assumed function during cytokinesis in higher eukaryotic cells², which do not have rigid cell walls and in which myosin is associated with the contractile rings of dividing cells. Actin has also been visualized at this neck region in *S. cerevisiae* by the immunofluorescent technique⁹. In this case, however, staining appeared immediately before bud emergence and at the final stage of cytokinesis, but was not detected during bud emergence, presumably because of structural changes in this region during budding. The pattern of staining observed with anti-myosin antibodies coincides with the appearance of 10-nm filaments in this region¹¹. It has been suggested by Kilmartin and Adams⁹ that the actin structures are not associated with the 10-nm filaments in yeast. However, other results (D. Botstein, personal communication) clearly demonstrate that actin is present at the neck region throughout the budding process. We are currently analysing yeast cell-division cycle (*cdc*) mutants that lack the 10-nm filaments at the restrictive temperature¹² to determine whether these filaments contain myosin.

Fig. 3 Fluorescence micrograph of yeast cells treated with anti-nematode myosin antibodies and anti-yeast tubulin antibodies. Immunofluorescence was performed using a modification of the method described by Kilmartin and Adams⁹. Cells were fixed with 3% formaldehyde and spheroplasts were prepared using 100 μ g ml⁻¹ zymolyase. Spheroplasts were incubated with: *a*, serum containing polyclonal anti-nematode myosin antibodies, followed by goat anti-rabbit IgG-FITC; *b*, non-immune serum followed by goat anti-rabbit IgG-FITC; *c*, monoclonal anti-yeast tubulin antibody⁹ followed by anti-rat IgG-FITC.

It has been widely speculated that, as well as its involvement in cytokinesis, myosin is a component of the cellular cytoskeleton. It has been proposed recently that actin participates in the transport and secretion of newly synthesized components for the budding cell wall in yeast^{9,10}. We hope that further analysis of mutants defective in the myosin gene will elucidate its interaction with actin and its function in the cell *in vivo*.

This work was supported by a project grant 8301270 to E.O. from the MRC. We thank M. Pocklington and C. Bagshaw for discussion, T. Harrison and E. Allan for assistance in preparing antibodies J. Karn for the polyclonal nematode antibodies, Ichiro Maruyama for the DNA probes and J. Kilmartin for yeast anti-tubulin and anti-actin antibodies.

India-Eurasia collision chronology

Patriat and Achache's analysis¹ of the convergence between India and Eurasia led them to conclude that India collided with Eurasia around anomaly 22 time (~50 Myr), confirming an earlier interpretation based on geological relationships in northwestern India that collision was pre-Middle Eocene², probably around anomaly 23 time³ (~52 Myr). Geological evidence from the Lhasa region^{4,5} also suggests that obduction of the suture-zone rocks onto the leading edge of India occurred there in the pre-Eocene interval, and that any significant shortening in the Lhasa Block was complete before the end of the Palaeocene⁶.

These observations pose a problem for Patriat and Achache's model¹ because in their Figs 1b and 4, 50 Myr ago southern Tibet was located some 7° north of the presently exposed northern boundary of India. Patriat and Achache¹ suggest that the 700 km of continental crust necessary to fill this gap was consumed first by subduction of ~400 km of Indian continent beneath southern Tibet from 50 to 44 Myr, and then by continued continental underthrusting and internal deformation to account for another 300 km of north-south shortening before 37 Myr. There are at least three problems with this model.

(1) Deformation in the supposed continental subduction and underthrust zone (Indus-Tsangpo suture) should be of Eocene age, rather than late Cretaceous or early Palaeocene as shown by field relationships^{4,5}.

(2) The now-vanished continental crust would have lain between the Tethyan Himalaya and southern Tibet, in which case the Tethyan Himalaya would have lain in the interior of the Indian continental block before collision, and not at its leading edge as is widely accepted^{2,6,7}.

(3) Southern Tibet would have had a much thicker than normal continental crust from mid-Eocene to present, in which case isostatic rebound would have led to a Palaeogene rise of the Tibetan plateau, for which there is no geological evidence.

These problems disappear if the pre-collisional shape of India is extended northwards to take account of its original size in Gondwanaland^{8,9}. A pre-collisional Greater India with its northern edge extending as far north of the exposed Indian Shield as the Kun Lun is today would not only have collided with southern Tibet by the postulated 50-Myr collision time, but could later have underthrust its broken-off leading edge, the Tethyan Himalaya, to produce the 70-km continental crust beneath Tibet. The underthrusting could have been as a series

of intracontinental slices¹⁰ rather than a single continental underthrust^{2,3}.

Recognition of the Tethyan Himalaya as the leading edge of Greater India obviates the necessity to postulate 700 km of Eocene continental subduction and underthrusting beneath southern Tibet, and raises the possibility that the threefold sequence of events suggested by Patriat and Achache occurred in almost exactly reverse order. Initial shortening within Eurasia is taken up by block rotation and lateral extrusion along sinistral strike-slip faults¹¹, then followed by crustal thickening through internal deformation and the beginning of continental underthrusting, and finally, when the continental underthrust zone is sufficiently well established, large-scale continental subduction occurs^{2,9}.

ACHACHE AND PATRIAT REPLY—Powell *et al.* estimate the pre-collisional shape of India after 'its original size in Gondwanaland'. This coincides with the present position of the Kun Lun belt. We think this method is highly questionable and thus, such an estimate must be considered as speculative.

The problems allegedly raised by our model call for the following comments: (1) The Cretaceous to Palaeocene F₁ deformation observed in the Yarlung Zangbo suture zone is related to northward subduction of oceanic crust^{1,2}. It is followed by a larger-scale although less intense younger F₂ deformation which can be associated with crustal subduction and shortening^{1,2}.

(2) The observation of Tethyan sediments in no way contradicts the model of subduction of 400 km of continental crust and only requires a 500-km-wide continental shelf north of India, before the collision. Whether this can still be considered as the so-called leading edge of India is merely a matter of vocabulary.

(3) The age of rise of the Tibetan plateau is still an open question. In particular, there is no valid evidence against a Palaeogene rebound.

We therefore do not see any real objection to our model in the comment by Powell *et al.* Furthermore, several field observations seem to contradict the reversed sequence of events suggested by these authors. First, a recent palaeomagnetic study³ of Tethyan sediments in Tibet has shown the amount of shortening in the MCT to be 400±400 km, thus much less than required by the proposed model. Second, structural and geochronological data indicate that significant underthrusting occurred in the Indian continent (Kangmar Thrust, Main Central Thrust, Main Boundary Thrust) between 45 and 35 Myr ago (see ref. 3). And third, the magnetic anomaly pattern in the South China Sea indicates that the motion along the Red River fault (and thus the extrusion of Indochina⁴) did not start until anomaly 13 time (36 Myr), that is, 15 Myr after the beginning of the collision (see ref. 5).

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

HUMAN TOXICOLOGY

An International Journal

- * publishes original papers of a high scientific standard on *all* aspects of Human Toxicology, embracing both animal research and studies with humans
- * presents invited commentaries on matters of current professional interest
- * regularly publishes abstracts of the proceedings of meetings of the British Toxicology Society
- * provides supplements as a forum for discussing the differing views on subjects of public concern in the areas of Human Toxicology
- * topical Editorials, lively Correspondence, informed Book Reviews

Intermediate Filament Monoclonals

Differentiate cell types
for more accurate
tumor characterization.

Intermediate filaments: protein specific, immunologically distinguishable components of the cytoskeletal structure of major cell types.¹ They are found in virtually all nucleated cells and retain their specific expression even during malignant change.

Because of this remarkable specificity, anti-intermediate filament antibodies provide a useful tool for identifying cell origins. (See chart below.)

Intermediate filament type	Expression in normal cells	Examples of corresponding tumors
vimentin	mesenchymal cells	most sarcomas, lymphomas, endotheliomas
desmin	muscle cells	rhabdomyosarcomas, leiomyosarcomas
cytokeratins	epithelial cells	most carcinomas
neurofilaments	neural cells	pheochromocytomas, esthesioneuroblastoma
GFAP	astrocytes	astrocytomas

Examples of *in vivo* normal cells and tumors recognized by intermediate filament antibodies.

Labsystems' quality control assures our monoclonals only react with their corresponding intermediate filament proteins.

These monoclonals can be used with either immunofluorescent or enzymatic techniques... with frozen or paraffin-embedded tissue samples.

For research use only. Not for diagnostic use.

Special offer: set of forty 35mm Intermediate Filament Reference Slides plus selected journal reprints.

For further information, contact your nearest Labsystems office.

CT1000 Cryotrans

The Hexland CT1000 Cryotrans system allows cryo observation to be carried out on most SEM's currently available. Adaption to older SEM's is also possible.

Monitoring of all cold areas is possible anytime, with accurate temperature control of the SEM cold stage to within $\pm 1^\circ\text{C}$. All nitrogen dewars are vacuum pumped, and the cold areas can be cooled to -195°C or lower within a few minutes.

- An efficient cold stage module. Separate anti-contaminator shielding in the SEM.
- Airlock and interface to the SEM chamber.
- Specimen preparation chamber with a cold stage, fracturing facility, sputter coating and high vacuum evaporative coating.
- Vacuum transfer device and rapid freezing chamber.
- Vacuum and temperature monitoring.

Image analysis takes off

from Geoff Jenkinson

Recent software developments are taking image analysis into new and uncharted areas of science.

THE basis of the image analysis method is well-known and it is not intended to describe this here. However, the architecture of the system is relevant in defining the capabilities of an image analysis system. A modern instrument, for example the Quantimet 920, will consist of a number of integrated components as shown in Fig. 1.

The video processor takes in the analogue video signal from the scanning source, either a TV-type scanner or a scanning electron microscope. The scan standards are chosen to optimize the resolution and signal potential of the source and give over 630,000 image points with up to 256 grey levels. A built-in shading corrector compensates for scanner and optical grey level variation. The resulting signal is converted to digital form and can be stored as a full grey-level image.

The 2-D array processor performs real-time image transformations to remove errors caused by optical and electronic effects which limit the rise-time of the video signal, to enhance fine detail, for example in grain boundaries, and to remove specimen-dependent shading. The image processor performs other digital signal processing tasks and also extracts a wide range of field and feature data parameters from the image. The image store can store multiple grey images at a variety of resolutions and binary images. These images may be roamed and zoomed and transferred to and from disk.

Software

Users of image analysis systems have an enormous variety of requirements. The software has to be structured to meet all these needs and can be broadly considered

Fig. 2 Image analysers can now be packaged together with a scanning electron microscope, as on this Quantiscan 922 from Cambridge Instruments.

as falling into three main types:

Turnkey application program. A program or set of programs is provided which requires only that the operator follows a sequence of prompts which appear on the display. This will be normally used for routine applications which only require the operator to make minor adjustments to settings of detection or for interactive image editing for example.

Interactive routine building. To create a new application solution the user is provided with a special ready-to-use interactive software package known as QUIPS. This allows the various image analysis facilities to be called up and the effect of selecting various combinations made immediately visible. Test results may be examined to decide if it is worthwhile proceeding to a more detailed analysis. In operation the primary image analysis functions are displayed on the control monitor and these are selected by means of a pointing finger which is manipulated via a digitizing tablet.

Software extensions. The potential of the system is not limited to the standard functions as described above. A PASCAL software package allows complete freedom of access to all data and images in the system, so that new functions and instructions can be defined and incorporated into the standard routines.

Application examples

Two applications have been chosen which illustrate the range of techniques required of image analysis systems. These are all in routine use on standard production instruments.

Receptor binding autoradiographs. In quantitative autoradiography in neurobiology and pharmacological research, image analysis provides facilities for region selection of the autoradiography, measuring radiation levels and colour-coding images. Image analysis can signifi-

cantly ease the interpretation of results and by means of its speed, make possible experiments which could not previously be contemplated.

In the study of receptor binding the general approach can be illustrated by quantifying the binding of a drug to rat forebrain sections. Adjacent sections are incubated both with and without a drug which displaces a radioligand from the binding site or sites which are being investigated. Thin sections of brain tissue are used to expose a tritium-sensitive film which produces an autoradiograph in which the radiation levels give a corresponding density on the film. Standards of radio-labelled tissue are also exposed on the film. A calibration curve is produced which converts the grey-level on the film to the quantity of the bound drug.

The adjacent sections produce images which represent total binding and non-specific binding of the drug. A single section of total binding is imaged at low magnification onto the TV camera of the image analyser and stored in its image memory. Corrections of non-uniform illumination and conversion to radiation via the calibration curve are made before storage. The image of the nonspecifically bound section is superimposed with the outline of the previous section and similarly stored. Subtraction of the nonspecific bound image from the total bound image now gives an image which represents the specifically bound component. The percent specific binding can now be determined by dividing the specific bound image by the totally bound image. Regions of interest may be outlined by means of the digitizing tablet and the mol per mg protein within the region determined.

An alternative method of measuring the radiation values is to use a higher magnification and dark-field illumination on a light microscope which allows the individual grains in the photographic emul-

Fig. 1 Block diagram of a modern image analysis system.

sion to be seen and hence counted. This method is used when smaller regions need to be identified or when the density of the autoradiograph is low.

Combined scanning electron microscopy and image analysis. The potential of combined scanning electron microscopes and image analysis systems has been acknowledged for some years. The SEM gives superior resolution and excellent contrast on many specimens which cannot be analysed by means of a light microscope. A variety of detectors is available for the SEM which form images corresponding to different properties of the specimen and which are suitable for image analysis. Up to now however it has been difficult to capitalize on this potential due to the relative complexities involved in connecting the two instruments together. It is now possible to fully integrate the capabilities of the electron optics and image analysers, as is done in the Quantiscan 922 system shown in Fig. 2. This analyser has a resolution better than 4nm in secondary electron imaging mode when fitted with a directly heated LaB₆ emitter producing an overall magnification range of 4× to 300,000×.

The SEM image is transferred directly to the image store in the image analysis system from where it can be continuously displayed on the screen of the analyser. Transfer rate is selectable from 0.3s up to 200s, and calibration of the measurements is made automatic by monitoring the SEM operating conditions.

When used in conjunction with an energy dispersive X-ray system the analytical potential is further extended. The X-ray information indicates the presence of particular elements in a specimen, and the importance of this is that it may be combined with the topographic and structural information from the image analysis to give a complete interpretation of the specimen.

Other applications

Image analysers can be used for many other applications and have found ready acceptance in quality control in fibre industries where they are used to measure the characteristics of synthetic fibres, in electronics to map the dislocation density in semiconductor wafers and to monitor oil contamination in hydraulic systems. In the field of metallurgy, where image analysers have been in use for more than two decades, their utility is being extended by the introduction of automatic charting.

There is also increasing demand for fast simple image analysers capable of routine particle sizing and counting and these are incorporating many of the features of their larger relatives. This will continue the downwards cost trend which will make image analysis available to an even greater range of users in the future. □

Geoff Jenkinson is at Cambridge Instruments Ltd, Rustat Road, Cambridge CB1 3QH, UK.

Image analysis and microscopy

A sampling of products from a simple magnifier to the latest in image analysis.

- Capable of analysing images from microscopes, video-tape recorders, drum scanners, photometers and photographs, Reichert-Jung's Polyscan offers maximum flexibility of image format without compromising access to the powerful software library. The system is programmable using either direct routines from an extensive menu or custom modifications entered via the image processing library. Polyscan will run automatically and uses a high resolution, low geometric distortion camera, capable of better than 1,000 lines, and computer-controlled beam blanking for image integration. Pseudocolour processing is supplied as standard and real colour is available as an option. Two CRTs are included in the system: a 12-inch black and white VDU for displaying user dialogue and programming; a 13-inch high resolution colour monitor for the image being analysed.

Reader Service No. 100.

Gentleman Jim for rapid freezing.

- A novel method for quick freezing tissue samples for electron microscopy is adopted in a new system from Pelco. 'Gentleman Jim' is an instrument which permits instant freezing of biological samples by dropping the selected tissue onto a polished surface of pure copper at liquid nitrogen temperature. Gentleman Jim does not permit bounce during contact as a special hydraulic system forces the sample tissue to maintain contact during the crucial initial moments of quick freezing. Excellent results have been obtained for the first 12 to 15 micrometres of tissue depth. Helium is unnecessary since liquid nitrogen produces satisfactory results. After freezing, dehydration by freeze substitution may be carried out.

Reader Service No. 101.

These notes are based on information provided by the manufacturers. To obtain further details about these products use the reader service card bound inside the journal.

- The DM54K image analyser from Digital Measurement Associates Ltd. provides a high speed low cost approach to obtaining quantitative measurements from subjective images. The system comprises a television camera interfaced to an Apple IIe computer via a custom interface enabling video images to be digitized in real time, approximately one fiftieth of a second. The interface expands the Apple working memory to 128K and also provides eighty-column text facility. It is supported by a suite of dedicated software providing a full range of image analysis features. The TV camera may be attached to a standard viewing system to image macro objects, photographic prints and so on. Alternatively a standard range of adaptors is available for light microscopes. TV images are digitized in real time to provide a detected matrix of 280 × 192 pixels. A possible 256 grey levels are available in either 'blacker than', 'whiter than' or 'grey slice' modes together with a programmable shading correction system to adjust for uneven background illumination. Area, end count, full feature count and intercept data are generated as a basis for a full stereological analysis.

Reader Service No. 102.

- The new 40-10 model image analyser from AMS (Analytical Measuring Systems) is available with a dedicated biological software package for applications such as colony counting, bacteria counting, breakpoint MIC determination, inhibition zone measurement, viral plaque counting and spiral plate counting. The VIDS II semi-automatic image analyser is a graphics tablet based system and is used in conjunction with an Apple computer and Epson printer. The scanner provided with the system can be mounted on any type of microscope or used with the AMS macro stand for macro-samples. With this system any sample that can be imaged with the camera can be "drawn round" and measured. Typical applications include analysis of histological sections, SEM and TEM micrograph measurements and particle size analysis.

Reader Service No. 103.

The AMS 40-10 image analyser.

IMMUNOLABELLING FOR ELECTRON MICROSCOPY

edited by J. M. Polak and I. M. Varndell

Immunolabelling for Electron Microscopy is a compilation of invited chapters written by highly experienced and active field workers, which documents established principles and current trends in all aspects of electron microscopical immunocytochemistry. The chapters cover the history of the technological achievements, all currently practised electron immunocytochemical techniques, often with innovative modifications, and the application of these procedures for the morphological identification of antigens from tulip plant viruses to man.

This volume is primarily directed towards the electron microscopist who has questions for which immunocytochemistry could provide the answer. The intended audience is, however, very much wider and taxonomists to cell biologists, endocrinologists to diagnostic pathologists, both in routine and research laboratories, will profit from the book's coverage of this rapidly emerging and important field.

A Nimbus microcomputer forms the basis for the latest image analysis package from Digithurst.

- As an alternative to supplying image analysis equipment for connection to existing microcomputers, Digithurst has introduced an image analysis system based around the Research Machine's Nimbus. The latest version of the Digithurst Micro-Sight is incorporated in the system which enables images to be captured at up to 512×512 resolution with 265 grey levels. Using standard graphics the image can be displayed at 256×256 with 16 grey levels on the Nimbus screen. The system uses an 80186 CPU running at 8MHz 320K of memory and twin floppy disk drives; hard disk drive versions are available together with networking options. The memory can be expanded up to 1 megabyte. Images captured by the system can be dumped to a printer or stored onto disk, they are also available to graphics packages which can manipulate and edit the displayed pictures in applications such as art, design, advertising, display and computer aided learning.

Reader Service No. 104.

- Raymond A. Lamb's Labstack filing system offers a wide range of stackable steel cabinets for storage of microscope slides, either vertically or horizontally in slotted racks. Transparency cabinets are also available as well as paraffin block filing cabinets with divided drawers to hold either System I embedding rings or System II embedding cassettes. These cabinets are in two sizes, either standard for floor stacking or half-depth for bench-top use. The drawers are provided with stops to prevent accidental removal although they can be removed and relocated. Accessories include spring spacers for initial filing before the mountant has hardened for contact storage, adaptors for holding larger slides in 26 mm wide drawers, different coloured location slips, transparency filing cards, slide wallets and dividers to file 76×26 mm slides in 52 mm wide drawers. System I embedding rings and System II embedding cassettes are included in the range together with cardboard boxes in varying sizes for unmounted blocks.

Reader Service No. 105.

- Philips Analytical has introduced a new Edax EDSCAN software package which provides a means of acquiring and presenting spatially related chemical information from a sample using a scanning electron microscope with attached Edax 9100 energy dispersive analyser. The package uses computer controlled microscope beam positioning to probe the specimen and collect from it X-ray and electron back-scattered signals quickly and efficiently. Collection beam geometries range from single spots to digitized line scans and area scans. Data is stored on disk and can, if required, be easily manipulated using simple arithmetic processing before presentation on one of a variety of available output devices. The Fortran-based EDSCAN software package is divided into two distinct functions: XSCN, devoted to X-ray signal collection, and ESCN for microscope signal acquisition.

Nunc's flask-come-slide.

- The Nunc SlideFlask is a combination of a cell culture flask and a microscopy slide. The bottom for the flask has exactly the same dimensions as a standard microscopy slide, giving a culture area of 9 cm^2 . It is manufactured from Nunclon Delta material for good cell adherence and optical clarity. The two flask parts are welded together, but slide and flask can be separated at any step in the preparation procedure after the cells have been cultured. The Nunc SlideFlask is specially designed for culture and preparation of cells and subsequent microscopic examination of the specimen under high power magnification (for applications such as chromosome examination, single cell autoradiography and single cell immunofluorescence).

Polaron's new sputterer.

• Although sputter coaters are now in routine use in the scanning electron microscopy laboratory for the coating of biological and other types of insulating materials with gold or some other noble metal, it has hitherto proved impossible to sputter materials such as aluminium or carbon which are necessary as a conducting coating for microprobe techniques. But the Polaron E5800 plasma enhanced a.c. sputtering system successfully deposits aluminium and other refractory materials. The plasma in the vicinity of the sputtering target is enhanced by an intense magnetic field; sputtering voltage is typically 300V, 150mA. Sputtering rates for aluminium are typically 60nm per second. If a gold target is used for routine SEM coating, then coating times can be as short as 15–20 seconds, avoiding heating problems on the sample surface.

StereoZoom 6 from Bausch & Lomb.

• StereoZoom 6, the latest microscope from Bausch & Lomb, has improved optics designed to match the colour correction response of the human eye. It provides clear, crisp images, true colour rendition and sharp contrast. Standard features include a one-to-six zoom system with an 0.67 to four basic magnification range, sharp resolving power at higher magnification, a wide field of view and exceptional depth of field at lower magnification (0.55 mm at 1.0 $\times$). The instrument's InstaZoom makes it possible to run through the entire zoom range with less than one-third of a revolution of the control, and its narrow, 56mm objective end allows it to be used in tight spots.

Reader Service No. 109.

• LKB-Produkter AB of Sweden has introduced a new high-precision glass-knifemaker (LKB 2178 KnifeMaker II) which allows the user to prepare 45° knives in either of two ways: in the traditional way or by applying the new 'balanced break' concept. No special skills are required to produce knives for semithin light microscopy sectioning or for cutting ultrathin sections for ultramicrotomy and cryo-ultramicrotomy. In the balanced break technique a standard 400-mm long strip of glass in any of three thicknesses (6.4, 8 or 10mm) is continuously broken up into equal halves to produce a full set of flat-sided 25 $\times$ 25 mm squares. The KnifeMaker II introduces two new scoring positions, to give four scoring choices. By enabling optimal corner-to-corner breaks, it simplifies the production of 45° angled cryo-knives. The holder also has adjustable click-steps, useful when preparing 40, 50, 55 and 60° knives.

Bench-top freeze drying by FTS.

• The Tis-U-Dry is a bench-top freeze dryer which allows the histologist to freeze dry and fix heat-sensitive tissues in one chamber. The Tis-U-Dry series has condenser configurations to -130°C and a temperature controllable tissue platten to -100°C . A formaldehyde heater is connected directly to the freeze dry chamber and an optional resin embedding accessory that is mounted in a vacuum top plate allows all steps to be performed directly in the Tis-U-Dry, which is produced by FTS Systems Inc.

Reader Service No. 111.

• New from Paar Scientific is an economical microscope warm-stage which can be fitted easily to virtually any model of microscope. The device consists of the stage itself and a control box on which any temperature from ambient up to 60°C can be set quickly and easily to appear on a digital display. The stage measures 75 mm by 50 mm with a 6 mm aperture and the sample or specimen is protected from induced currents by a bifilar heating element specially constructed of a foil material which covers the entire stage area to prevent cold spots.

Reader Service No. 112.

The Olympus IMT-2.

• New from Olympus is the IMT-2 inverted research microscope specially designed for the examination of cell cultures. Attachments can be fitted to the IMT-2 for brightfield, phase contrast, differential interference contrast and fluorescent observations. Switch-over between these different observation methods is fast and simple, and a fixed stage system assures reliability during micro-manipulation. The microscope features an automatic exposure 35 mm camera with the facility to accept further camera attachments.

Reader Service No. 113.

• Two recent publications by Olympus Optical are available free of charge from Gallenkamp, the company's UK agents. The first, *Photomicrography*, is intended for scientists who have never taken a photograph down a microscope but also for experienced photomicroscopists who would like to improve their techniques. The second booklet, *Fluorescence Techniques in Microscopy* covers selection of fluorescence equipment, filters and methodology. Write to Olympus Department, Gallenkamp, Belton Road West, Loughborough LE11 0TR, stating which booklet is required.

Reader Service No. 114.

The Nikon Microphot-PX is equipped with a sophisticated built-in automatic exposure photomicrographic system, and a wide range of functions for quantitative microscopy. Use the Reader Service Card (no.115) for full details.

CONVENIENT-INFORMATIVE-TIMELY-PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1. You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2. You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information... the latest instrumentation... marketing breakthroughs... funding sources... new technologies... patents and licences... profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3. You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4. You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

U.S.A.: BIO/TECHNOLOGY

Why this magazine and more than 1,000 others let us go over their books once a year.

Some magazines, we're sorry to say, keep their readers undercover. They steadfastly refuse to let BPA (Business Publications Audit of Circulation, Inc.) or any other independent, not-for-profit organization audit their circulation records.

On the other hand, over 1,000 publications (like this one) belong to BPA. Once a year, BPA auditors examine and verify the accuracy of our circulation records.

This audit provides the name, company, industry and job title of every reader each publication reaches. The information helps advertisers to determine if they are saying the right thing to the right people in the right place.

It also helps somebody else important: you. Because the more a publication and its advertisers know about you, the better they can provide you with articles and advertisements that meet your informational needs.

BPA. For readers it stands for meaningful information. For advertisers it stands for meaningful readers. Business Publications Audit of Circulation, Inc.
360 Park Ave. So., New York, NY 10010.

 **BPA**
MEDIA INTELLIGENCE

• The Carl Zeiss Jena range of stereomicroscopes now includes the GSM, a light but robust stereomicroscope of high optical performance constructed following the Greenough principle. A twin lens slide allows rapid change of magnification and the extensive range of accessories allows various modes of illumination and measurement. The Zeiss Technival 2 is a high performance stereomicroscope with a five step magnification changer giving a 10:1 overall factor. It is a modular system giving a high degree of flexibility in magnification, lighting and photographic attachments. Most of the accessories for this instrument also suit the Citoval 2, a zoom stereomicroscope with a range of 10:1.

Reader Service No. 116.

Artek's new camera and monitor.

• Artek Systems Corporation has developed a 700-line camera and 700-line monitor for image analysis, dimensional measurement, particle analysis and visual inspection. A wide selection of image tubes is available for a variety of applications including easy viewing of microscopic samples. The camera and monitor system are compatible with Artek's image analysers and new Video Micrometer and Reticle Generator.

Reader Service No. 117.

Pocket magnification from Microtec.

• An extremely highly corrected 10× pocket magnifier has been added to the Microtec range of magnifiers. The lens construction is a new design which enables the high correction to be achieved with lenses over 20mm in diameter. The magnifier has a chromed brass frame and is supplied complete with a hide case.

Reader Service No. 118.

The Vias workstation complete with digitizing tablet.

• Vias is a complete video image analysis workstation which includes both a flexible statistical package and a digitizing tablet. Featuring an easily accessible, completely menu-driven computer program, this system quickly and easily summarizes and performs complex morphometric calculations in any scale or coordinate system. Vias is available from Ted Pella Inc. of Tustin, California.

Reader Service No. 119.

TEM preparation by 'dimpling'.

• The 'Dimpler' is a new prethinning instrument for TEM specimen preparation. Taking a 2.3mm or 3mm diameter specimen with a thickness of 100 micrometres or more, the VCR Dimpler D500 will delicately grind and polish a 'dimple' into the centre of the specimen, leaving a large area which is close to electron transparency. The perimeter of the disk is polished flat but remains in the form of a thicker rim so the specimen can be handled with more stability and greatly reduced risk of damage. It is common to achieve a 95% successful specimen yield. A variety of materials can be 'dimpled' — from the hard ceramics, glasses, quartz, sapphire and silicon, to the soft III-V semiconductor materials such as gallium arsenide or indium phosphide. The Dimpler Model D500 is available in Europe through Testbourne Ltd.

Reader Service No. 120.

• The Ion Tech FAB 306A fast atom bombardment specimen milling module extends the scope for specimen preparation techniques for both transmission and scanning electron microscope work. As well as milling conventional materials such as metals, ceramics and glasses, this new FAB equipped atom milling module enables more exotic materials to be thinned safely, thus extending the process into the latest semiconductor, polymer and biological technologies. Materials such as gallium arsenide, silicon oxides and many other very sensitive specimens — even delicate biological structures such as brain cells — can be processed in this new instrument. The FAB 306A combines improved wide dynamic range fast atom guns which produce beams from very low to high current density equivalents of charge free atoms with an efficient liquid nitrogen cooled specimen stage. Both charge and radiation damage are thus greatly reduced and a sensitive automatic terminator allows the milling process to be stopped instantly as desired. A wide beam atom gun facility also enables large area SEM specimens to be surface etched and removes smears and debris caused by mechanical polishing or other physical or chemical preparation techniques.

Reader Service No. 121.

TEM and SEM preparation using fast atoms.

Education's response to adversity

from Richard Pearson

The small-print in the UK government's recent review of the future of higher education is worthy of close examination.

THE UK government's long awaited 'Green Paper', *The Development of Higher Education into the 1990s*, has been widely criticized for its lack of originality and new ideas. But students, educationalists and employers alike will ignore it at their peril. If the final policy statement appearing in 1986 after the period of consultation follows the expected pattern, then many students may have their higher education aspirations frustrated, teachers will have increased workloads and decreased job opportunities, and while many employers will gain from the likely increase in the output of industrially relevant graduates, they may face a growing shortage of good generalists. Driven by the twin pressures of financial restraint and the demographic change which will significantly reduce the 18-year-old cohort over the next ten years, the paper sets out the government's expected priorities for higher education to the end of the century, a key priority being to make higher education more responsive to the needs of the economy.

It is important to get the demographic influence in perspective. There are two features that everyone agrees on. First, the major source of entrants to higher education will continue to be the 18-21-year-old population, and second, the size of this cohort will fall by one-third over the next decade, with most of this fall coming in the early 1990s.

In 1983 the Department of Education and Science (DES) published details of its then current thinking on the future demand for higher education. The report led to widespread comment and criticism from, amongst others, the Association of University Teachers, the Royal Society, the Royal Statistical Society and the Committee of Vice-Chancellors and Principals, who all agreed that DES had taken insufficient account of the rising proportion of women and mature entrants wishing to enter higher education, and the social class differential in the changing birth rate. In particular, it was noted that the birth rate for social classes I and II, which has provided nearly two-thirds of university entrants in the past, rose during much of the relevant period and as such the overall fall in student demand would not be as great as simple demographic trends suggested. There was also criticism that that no allowance had been made for policies that might increase the participation from working class families, or improve accessibility for mature students.

In the light of these criticisms, the DES forecasts were revised in 1984. The key figures are that the number of 18-year-olds in the population will fall from 914,000 in 1984 to a trough of 613,000 in 1995 before rising to 681,000 in the year 2000. Two projections of qualified demand are given by DES (Fig. 1). The projection, Variant X, assumes that student demand will continue at the levels prevailing in 1981-82, and that women will continue to catch up with men in their degree of participation in higher education. DES assumes, however, that the qualified demand index for women will

Fig. 1 Projections, from the DES report, of the total number of home initial entrants for the academic years 1983/4 to 1999/2000. Variant Y is the revised version.

not exceed 85 per cent of the observed level for men.

Variant Y, revised again in January 1985, assumes that student demand will continue at the levels observed in 1983, after the public expenditure cuts had caused some redistribution of higher education places. Both variants are based on assumptions about the prevailing real value of student grants and the influence of various social and economic circumstances, including labour market opportunities for graduates. DES concedes that, by 1999, actual student demand could be outside the limits set by Variants X and Y. The figures suggest a fall in student demand over the period to 1995 of about one-fifth.

For young home initial entrants to higher education (aged under 21 years), Variant X shows demand rising slightly to a peak of 134,500 in 1985 before falling back to 107,500 in 1994 and rising again to 117,700 in 1999. It is assumed here that the age participation index (API) will rise from 14.4 per cent of the age group to 16.9 per cent by 1999. Variant Y anticipated that young entrant demand had peaked in 1983-8, and that the peak age participation index assumed (for 1999) is 13.9 per cent of the age group.

Mature entrants have to be added to these totals, and the DES projections pro-

vide for a small growth from 37,500 in 1983-84 to about 40,000-43,000 mature entrants for the academic year 1989-90 and about the same number in 1994.

The government's current expenditure plans assume that expenditure will be available to meet a level of demand equal to variant Y. The University Grants Committee, interpreting these figures, has said that universities should plan on the assumption of a 2 per cent per annum cut in resources until 1990. This could be equivalent to the closure of a major institution each year.

A key theme of the green paper is meeting the needs of the economy which is seen to require a switch in places towards science and technology subjects. There is, however, some doubt whether suitably qualified and interested students will exist to fill the additional places. The paper finds it remarkable that the public sector institutions cannot fill their current places in science and technology subjects. Student interest in science and technology will therefore have to increase significantly over the next few years if it is to counteract the downward demographic trends and allow for the increased number of places to be filled.

Perhaps the most profound and unexpected part of the green paper is the appendix in which performance measures are proposed to help evaluate the effectiveness of individual institutions. Costs per student, years per graduate, cost per graduate, non-completion rates, entry qualifications, and initial labour market success are all factors to be measured. These in turn are consolidated into a 'rate of return' which, it is argued, can be used in the future to measure not only differences across the binary line, but also between institutions, and between subjects and departments within institutions. On the research side DES sees measuring outputs as rather harder, for example, in measuring the 'quality' of a book or an article, so it is working on ways of measuring inputs to research and their relationships to teaching.

Performance indicators may in due course prove to be even more controversial than the policy perspective, and it will be interesting to see how the debate about the future of higher education develops over the next year. □

SENIOR MLSO (Microbiology)

Applicants are invited for the above post to join a team studying the microbiological aspects of dental caries and periodontal diseases in the Dental Research Unit of the Royal College of Surgeons, at Downe, near Orpington, Kent.

The duties are mainly isolation and identification of anaerobic bacteria, including spirochaetes, from dental plaque. He or she will be expected to make a significant contribution to the research programme of the Unit.

Qualifications: MI Biology, FIMLS in Microbiology or Bacteriology or equivalent. Salary according to qualifications and experience.

For an application form and further particulars please contact the Personnel Officer, Royal College of Surgeons of England, 35-43 Lincoln's Inn Fields, London, WC2A 3PN (Tel 01-405-3473 X136).
(7009)A

NORTH WEST HERTFORDSHIRE HEALTH AUTHORITY HARPERBURY HOSPITAL Harper Lane, Shenley, Radlett, Herts BASIC GRADE CLINICAL CYTOGENETICIST KENNEDY GALTON CENTRE

Candidates should have a good Honours Degree in Genetics or a biological subject. Experience of human chromosome techniques an advantage.

Salary: £6,559 to £8,725 plus £527 London Weighting.

Application forms/job description, contact Mrs Z Owen, telephone Radlett 4861 ext 22.

Closing date 19th July 1985.

Clinical Research Associate

Cardiovascular Unit Greenford, Middlesex

c.£14,000 (inclusive) plus car

Glaxo Pharmaceuticals, part of the highly successful Glaxo Group, are responsible for the manufacture and sale of pharmaceuticals in the United Kingdom.

We are currently seeking an experienced Clinical Research Associate to join our Clinical Research Division, based at Greenford, Middlesex. The work of the Division covers registration trials on line extension world-wide, trials of international marketing importance, and trials of local interest to Glaxo's overseas companies.

Reporting to a Clinical Research Physician, the successful applicant will be responsible for designing, organising and monitoring clinical trials – phases 3 and 4 – on specific topics related to the cardiovascular clinical research area. Travel, both in the United Kingdom and overseas, is a necessary part of the job and a company car will be provided.

Candidates should possess a post-graduate qualification in a scientific discipline, together with two to three years' relevant experience. The ability to communicate effectively, both verbally and in writing is essential.

Excellent conditions of employment include company bonus scheme, 5 weeks' holiday, non-contributory pension scheme, sports and social facilities, and generous relocation assistance where appropriate.

Please write or telephone for an application form to: Mr. I. Campbell, Senior Personnel Officer,

LANCASHIRE POLYTECHNIC AT PRESTON

**Faculty of Science
School of Applied Biology**

Applications are invited for the following posts.

RESEARCH ASSISTANT —

Molecular Genetics of Cyanobacteria (REF. AA/263)

To investigate genetic adaptations resulting in variations of the photosynthetic apparatus and will involve genetic engineering of cyanobacteria.

RESEARCH ASSISTANT —

Biochemistry of Photosynthesis (REF. AA/264)

To investigate the role of CA2+ in Photosynthesis electron transport, especially of photosystem 2.

RESEARCH ASSISTANT —

Biodeterioration (REF. AA/265)

To investigate the formation of biofilms on surfaces of aqueous industrial systems and metal working fluids.

SERC RESEARCH STUDENT —

Plant Cell Immobilization (REF. AA/266)

To investigate the effects of immobilization on secondary metabolite production and/or heavy metal tolerance or unicellular algae.

SERC RESEARCH STUDENT —

Regulation of Myocardial contractility (REF. AA/267)

To investigate two cardioactive factors which have marked effects on myocardial contraction and may be associated with some cardiovascular disorders

Research Assistant appointments will be limited term contracts for a maximum of three years.

Candidates for all posts will be expected to register for a higher degree and should hold at least an upper second class honours degree.

Salary for Research Assistant: \$6,405 — \$7,176 (under review).

Further details and application forms quoting the appropriate reference number obtainable from the Personnel Office, Lancashire Polytechnic, Preston, PR1 2TQ. Tel. (0772) 262027.

Closing date: 15 July 1985.

RESEARCH STAFF
DIVISION OF INFORMATION TECHNOLOGY
(Several positions)
\$A26,001 — \$A54,029

**FOUNDATION LABORATORIES IN
 SYDNEY AND MELBOURNE**
FIELDS OF INTEREST:

Software engineering
Computer networks
Man machine interfaces
Information management
Device and systems hardware
technologies

GENERAL: The Division of Information Technology is forming two laboratories at sites in Sydney and Melbourne which will support collaborative research and development programmes in one or more of the fields listed above. The Sydney laboratory will specialise in the software engineering area and that at Melbourne in aspects of computer network research. In the formative first year, recruitment will be confined to the establishment of, at most, three units of two or three research and scientific staff at each site which will act as the nuclei for larger collaborative projects with staff from local industrial and academic research centres. These small teams will be led by eminent scientists/engineers and supported by other staff drawn from the mix of disciplines listed.

DUTIES: The senior appointees will initiate and direct programs of research in the areas outlined above and will play a major role in defining the most productive research directions for the Division in these areas. They will collaborate extensively with academia and industry to promote technology resulting from the research activities.

QUALIFICATIONS: A PhD degree or equivalent in Computer Science, Electronic or Communications Engineering, and proven research ability is required for all research scientist positions. Applicants for the senior posts should also be able to offer a distinguished record of research accomplishments and give evidence of research leadership ability of a high order. Appointment at the Senior Principal Research Scientist or Chief Research Scientist levels requires the appointee to have an international reputation.

TENURE: Appointment is available on either a fixed-term or indefinite basis and applications should state the candidate's preference. Australian Government Superannuation benefits available. To facilitate collaboration with the industrial and academic communities provision will be made for secondments in both directions.

SALARY:

Research Scientist	\$A26,001 — \$A32,083
Senior Research Scientist	\$A33,209 — \$A38,243
Principal Research Scientist	\$A39,692 — \$A45,083
Senior Principal Research Scientist	\$A47,501 — \$A52,212
Chief Research Scientist	\$A54,029

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two referees and quoting reference No A1963, should be directed to:

NEUROENDOCRINOLOGIST

Department of Physiology

QUEEN'S UNIVERSITY

A vacancy exists for an experienced neuroendocrinologist. The preferred applicant should have the Ph.D. and/or the M.D. degree, several years teaching experience and a record of independent research of high quality. The applicant will be expected to lead an active research program and to participate in undergraduate and graduate teaching. The facilities for research are outstanding and the appointment is a regular one under tenure regulations. The appointment will be made at a level appropriate to the candidate's qualifications.

Applications are encouraged from candidates of either sex. Applicants should submit a curriculum vitae, a brief statement of their research interests and objectives, selected reprints, and the names of three referees from whom a confidential assessment of research and teaching abilities may be obtained to: Dr. V. C. Abrahams, Department of Physiology, Queen's University, Kingston, Ontario, Canada K7L 3N6. (Second Advertisement).

Marketing Manager Agrochemicals

c.£17,500 + car

Herts

This is a rare opportunity to run a small but growing agrochemicals business, operating within one of the most respected market leaders in the animal health field.

Reporting to the Divisional Director, your role will encompass all the classical marketing activities together with a very strong technical contribution. The responsibilities and demands of the position are both considerable and wide ranging – matched only perhaps by the personal opportunities and career potential.

Aged ideally 28-32, you will be a graduate in Biological or Agricultural Sciences. While your technical competence and credibility must be beyond question, it is essential that you also have some practical experience of and demonstrable aptitude for the commercial realities of the marketplace. Last, but by no means least, you must have the ambition and persuasiveness to drive the business forward, building soundly on its very strong base.

Call Richard Goldie on (0992) 552552 if an initial discussion would be helpful before writing to me, enclosing a brief CV together with an indication of recent salary progression, at Macmillan Davies Personnel Consultants, The Old Vaults, Parliament Square, Hertford, Herts. SG14 1PU.

(7052)A

Max-Planck-Institut für Biochemie Department of Membrane Biochemistry POST-DOCTORAL FELLOW IN MOLECULAR BIOLOGY

Applications will be accepted for a position in a group concerned with light-regulated gene expression in *Physarum*. Projects include cloning and sequencing of regulated genes as well as transcription in isolated nuclei/chromatin. Expertise in molecular biology techniques is essential. Preference will be shown to candidates having experience in lambda cloning.

The appointment is supported by the Deutsche Forschungsgemeinschaft and will be for 18 months starting as soon as possible. The salary will be in the range of DM 2000,—. Applications together with CV, research experience and interest, list of publications and the name of two referees should be sent to Dr. Thomas Schreckenbach, Max-Planck-Institut für Biochemie, 8033 Martinsried, FRG before 30th August. (W1990)A

UNIVERSITY OF THE SAARLAND (FRG), DEPARTMENT OF PHYSIOLOGY

TWO POSTDOCTORAL POSITIONS

to work on the electrophysiology of single myelinated nerve fibres (voltage clamp, fluctuation analysis, gating currents).

The project is supported by two project grants from the DFG. The appointments are from 1st January 1986 to 31 December 1987, with possible prolongation. The salary is about DM 55,000 — DM 65,000 per annum, depending on age and family status.

Applications (including a curriculum vitae and the names of two referees) should be sent to Prof. H. Meves or Prof. B. Neumcke, I. Physiologisches Institut der Universität des Saarlandes, D — 6650 Homburg/Saar, Federal Republic of Germany. (W1994)A

UNIVERSITY OF LONDON Royal Holloway and Bedford New College

Readership in Environmental Systems Analysis and Control (within the Department of Geography)

The Senate invite applications for the above post from established researchers to initiate and develop research and teaching in environmental systems analysis using dynamical modelling techniques. Applications (10 copies) should be submitted to the Academic Register (N), University of London, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained.

Closing date for receipt of applications — 16 August 1985. (7012)A

UNIVERSITY OF QUEENSLAND READER IN SOIL PHYSICS (tenured) — AGRICULTURE

To teach Soil Physics at both undergraduate and postgraduate level, supervise postgraduate students and develop research. Applicants should have a Ph.D. in Soil Physics and considerable experience in teaching and research in Soil Physics. Experience with Australian soils, in particular Vertisols, an advantage.

Salary per annum: \$A43,929

Closing date: 14th June, 1985. Ref. 14185.

Additional information and application forms are available from the Secretary-General, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

CSIRO

AUSTRALIA

MOLECULAR BIOLOGIST

\$26,001 — \$38,243

DIVISION OF PROTEIN CHEMISTRY

PARKVILLE VIC, AUSTRALIA

FIELD: Molecular Biology/Genetic Engineering.

GENERAL: The Division of Protein Chemistry conducts scientific research on the structure and function of proteins and their production via biotechnology and synthetic routes. It has a total staff of 116. The appointee will be a member of the Program Applied Protein and Gene Technology which has 22 professional scientists working on biotechnology based projects. Current research projects within the Program include the production of subunit and peptide vaccines, diagnostic probes, and the genetic improvement of industrial microorganisms. Besides recombinant DNA techniques, scientists in the Division have expertise in protein and peptide chemistry, immunochemistry, X-ray crystallography, organic chemistry, cell biology and electron microscopy. The Division is very well equipped and has excellent facilities for recombinant DNA research. The Division is situated in close proximity to some of the major bio-medical research institutes in Australia: Melbourne University, CSIRO Division of Animal Health, and the Commonwealth Serum Laboratories. There is excellent potential for collaboration with scientists in the above institutions and elsewhere both within and outside the CSIRO. Adequate technical assistance will be provided to the applicant.

DUTIES: The appointee will join a multidisciplinary research team involved in the production of significant new biological products focussing initially on a vaccine for an important disease of poultry.

Specific duties would include the construction and modification of useful expression vectors for the production of the avian antigen vaccine and other high value proteins in microbial systems such as yeast, *E. coli* and other bacteria.

QUALIFICATIONS: A PhD or equivalent qualification and post-doctoral experience in a relevant field, and demonstrated research ability. Experience in recombinant DNA research is essential. Applicants should preferably have prior experience in the construction and use of yeast and/or bacterial expression vectors.

TENURE: Indefinite with Australian Government superannuation benefits available. However, applicants who would prefer a fixed term appointment of 3-5 years will be considered.

NOTE; Indefinite Appointment attracts assistance with travel and removal costs for appointee and immediate family.

Term Appointment attracts these benefits plus assistance with relocation costs at the end of the term.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference number A2488, should be directed to:

THE UNIVERSITY OF LANCASTER

Department of Environmental Science

ENVIRONMENTAL RADIOACTIVITY

Applications are invited for the post of Research Associate to work with Dr. J. Hamilton-Taylor and Dr. M. Kelly on a study of transuranic elements in the estuarine environment. Ideally, applicants should possess Ph.D. and have research experience in environmental chemistry or geochemistry, although candidates with alternative qualifications will be considered. The appointment would be for six months from 1 October 1985, although funds for additional periods have been applied for. Salary up to the £10,330 point of Research 1A scale (£7,520 — £12,150 under review).

For further details and application form, please write to the Establishment Office, (quoting reference LSSO/B) University House, Bailrigg, Lancaster LA1 4YW where applications (five copies) naming three referees should be sent to arrive NOT LATER THAN 1 August 1985.
(7047)A

LEONHARD PROFESSORSHIP IN SOLID STATE DEVICE ENGINEERING

Applications and nominations are invited for a recently endowed professorship in Solid State Device Engineering within the Department of Electrical Engineering at The Pennsylvania State University. Applicants should have an earned doctorate in electrical engineering, engineering physics, or a related field, and have demonstrated the ability to conduct research and teaching in the field of Solid State Device and Microelectronics. Strong leadership qualities are also emphasized.

The successful applicant is expected to join the existing effort in solid state device research and help expand and develop it into one of prominence in both research and instruction. The College of Engineering has made substantial commitment to support this program including updating of the laboratory facilities and new faculty hiring.

Currently, research in the solid state device and related materials area includes research in silicon device processing, such as plasma and reactive ion etching, thermal nitridation of silicon and various oxide research including ultra-thin oxides, and defect control. In addition, research in III-V device area includes material defects, electrical noise and performance improvement of micron and sub-micron structures.

Combined research in the solid state device area typically amounts to about one million dollars annually. Collaborative research opportunities exist with the Materials Science department, Engineering Science and Mechanics department, the Chemistry and the Physics departments and the Materials Research Laboratory at Penn State.

Résumés, nominations, or inquiries should be directed to the following address by no later than September 15, 1985, or until a suitable candidate is selected.

Chairperson, Leonhard Professor Search Committee

(NW1910)A

The European Molecular Biology Laboratory, an international research institute situated in Heidelberg, West Germany, invites applicants for two vacancies in the protein crystallography group headed by Dr. K.S. Wilson at the Laboratory's Outstation at the Deutsches Elektronensynchrotron (DESY) site in Hamburg

(PROTEIN) CRYSTALLOGRAPHERS/ PHYSICIST

The Outstation has developed advanced instrumentation for the use of synchrotron X-ray radiation in structural biology: protein crystallography, fibre and solution diffraction, X-ray spectroscopy (EXAFS)

The facilities are used by many groups mainly from the Member States. The candidates will be expected to engage in research projects, mostly on a collaborative basis with outside groups, which make use of the outstanding properties of synchrotron radiation (high intensity, wavelength tunability, polarization and time structure) for protein crystallography. Besides these activities, they will also assist outside groups with protein crystallographic data collection.

For the first position, experience in experimental physics or crystallography is required as the successful candidate will be responsible for the instruments for protein crystallography at the Outstation.

For the second position, the emphasis will be on the development of software for data collection with electronic area detectors. Experience in real time programming of instruments like four-circle diffractometers will be an asset.

An above-average salary will be offered to the successful candidate. Certain allowances are payable in addition, depending on personal circumstances. An initial contract of three years' duration, which can be renewed, will be offered.

Please write briefly for an application form, quoting reference No 84/8 & 9 to

EMBL,
Personnel Section,

(W2008)A

EMBL

THE WORLD HEALTH ORGANIZATION
invites applications for the post of
**SCIENTIST (RESPONSIBLE OFFICE, RESEARCH
AND DEVELOPMENT)**

with its Special Programme for Research and Training in Tropical Diseases, Geneva. The incumbent will coordinate the strategic planning of the Research and Development operations of the Special Programme for Research and Training in Tropical Diseases (TDR) and the execution of the Research and Development plans as recommended by the Scientific and Technical Advisory Committee (STAC) and approved by the Joint Coordinating Board (JCB), and provide secretariat services for meetings of the STAC and its sub-committees; coordinate the planning of individual Scientific Working Groups (SWGs) and exploit opportunities for synergy, maintain programme balance and cohesion and avoid duplication among the groups; monitor and evaluate effectiveness and efficiency of research and development undertaken by SWGs.

Qualifications and Experience: A degree in medicine or a biomedical science degree at the doctorate level from a medical school or a university of recognized standing. Research qualifications to a doctorate level in association with medical degree or post-doctoral qualifications if primary doctorate degree is non-medical. At national level, at least 10 years' experience in biomedical research, including: (a) independent contributions to scientific knowledge; (b) direct involvement in research and authorship of a substantial number of scientific publications in refereed journals; (c) directing a research group; (d) research administration and participation in the work of research funding bodies; (e) teaching and training of researchers, both through the organization of training courses and the supervision of doctorate students. At international level: 5 years' experience in the planning and organization of research in an international framework. Excellent knowledge of English or French and a working knowledge of the other language.

The salary scale ranges from US\$ 42,594 (single) and from US\$ 46,125 (with dependents) net of tax per annum. Applications are invited from candidates of either sex — applications from women are encouraged. Qualified candidates should send their detailed curriculum vitae not later than mid July 1985 quoting "TDR/85" to:

Personnel (MPR), World Health Organization, CH — 1211 Geneva 27

Only those candidates under serious consideration will be contacted.

**UNIVERSITY OF ULSTER
'NEW BLOOD' LECTURESHIP IN
EXPERIMENTAL SOLID STATE PHYSICS**

at Coleraine, Ref: C85/126

To undertake research in the physics of low-dimensional systems, surface physics spectroscopies or low temperature (millikelvin) physics or in some other area of condensed matter physics, and to contribute to the teaching in the Physics and Electronics programmes of the Department of Physics.

Applicants should hold a good honours degree and a higher degree in Physics and should have had appropriate research experience. In accordance with the New Blood appointments scheme, applicants should normally be under the age of 35 years and should not hold permanent university appointments in the United Kingdom.

Salary will be determined by age, qualifications and experience within the range £7,520 — £14,925 per annum (under review).

Further details are available from the Staffing Office, University of Ulster at Coleraine, Cromore Road, Coleraine, Co Londonderry BT52 1SA (Telephone Coleraine (0265) 4141, Ext 225. Telex 747597) to whom applications, including a full curriculum vitae and the names and addresses of three referees, should be sent not later than 2 August 1985. (6993)A

THE MAX-PLANCK-GESELLSCHAFT
invites applications for the position of a
RESEARCH GROUP LEADER

from promising young scientists who have achieved a degree of international recognition in their field, preferably in

Cell Biology, Developmental Biology, or Neurobiology

The successful applicant will be expected to conduct a vigorous, original and independent research programme at the

Friedrich-Miescher Laboratory in Tübingen

The position is for 5 years, carries a salary of 65-70,000 DM p.a. (C3 scale of the Bundes-Besoldungsgesetz) and is roughly equivalent to an Assistant Professorship (US) or University Lectureship (UK). There is no teaching commitment.

The group will have modern laboratory facilities, operating expenses, and funding for scientific and technical co-workers.

Applications, including a tabular curriculum vitae, list of publications, and a description of major scientific achievements and future research plans, should be submitted until end of September 1985 to:

Max-Planck-Gesellschaft, zur Förderung der Wissenschaften e.V., — Generalverwaltung —, Postfach 647, D-8000 München 1. (W1991)A

to prepare histological sections for research and teaching. Training for specialist techniques needed will be given.

Candidates must possess ONC or appropriate equivalent as minimum qualification plus seven years histology experience.

Salary within range £6,106 — £7,024 per annum (under review).

Application forms may be obtained from the Registrar, the University, PO Box 147, Liverpool, L69 3BX.

Quote Ref: RV/134/N. (7022)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF ZOOLOGY Applications are invited for a post of GRADUATE RESEARCH ASSISTANT

to work on the developmental biology of *Drosophila* imaginal discs, using the techniques of tissue culture and ultrastructure. Candidates should have a first or second class Honours degree in Biology or Zoology. Some knowledge of developmental or cell biology and practical experience of transmission electron microscopy, would be an advantage. This post is funded by the Science and Engineering Research Council for approx 12 months. Salary within range £6,600 — £7,055 per annum, plus USS.

Applications, with full curriculum vitae and names of two referees, should be sent as soon as possible to Dr M J Milner, Department of Zoology, Bute Buildings, The University, St Andrews, Fife, KY16 9TS. (6996)A

IMPERIAL COLLEGE (University of London) SUBMICRON LITHOGRAPHY

We are seeking a scientist/engineer who has recently obtained a doctorate to work on electron beam stimulated decomposition of inorganic solids for use as resists in sub-micron lithography. A strong ability in experimental work plus a facility with programming is highly desirable. The appointment is, in the first instance, for one year at a stipend of £8,753 (this includes London Weighting).

Write to Professor Mino Green, Dept of Electrical Engineering, Imperial College, Exhibition Road, London, SW7 2BT. (7024)A

CAMBERWELL HEALTH AUTHORITY King's College Hospital CYTOGENETICIST

DEPARTMENT OF HAEMATOLOGY

Salary: £7,021 — £9,395 pa inc (depending on degree).

Required to perform cytogenetic analysis on samples from patients with leukaemias, lymphomas and related haematological disorders. The Department provides a cytogenetic service to haematologists throughout the South East Thames Region. Previous experience of cytogenetics of leukaemias would be an advantage. An appropriate science degree is essential.

For further details, contact Mr G J Mufti or Professor A J Bellingham, 01-274 6222 extension 2013 or 2045. Application forms and job description available from Unit Personnel Department, King's College Hospital, Denmark Hill, London SE5 9RS, telephone 01-274 6222 extension 2751/2254. (7026)A

WASHINGTON UNIVERSITY ST. LOUIS, MISSOURI POSTDOCTORAL POSITIONS

Interactive and broadly based senior research group interested in biological problems associated with BONE and BONE MARROW CELLS invited well qualified, recent doctoral graduates to apply for laboratory positions at the postdoctoral level. Research areas of particular interest to the group include:

1. Hormonal and immune regulation of bone remodeling
2. Mechanisms of collagen and bone matrix degradation
3. Gene expression in bone forming and resorbing cells
4. Mitogenic and chemotactic properties of thrombin and other clotting proteins.
5. Origin and differentiation of osteoblasts and osteoclasts
6. Vitamin D in cell maturation and immune function

Ideal candidates should have some prior laboratory experience with both contemporary biochemical and cell biological techniques. Partial and full stipends are available depending upon the citizenship status of the individual applicant.

Interested parties should submit a curriculum vitae, the names and addresses of three references, and a brief statement of research experience and goals to: Prof. George Wilner, Box 8050, Washington University School of Medicine, St. Louis, Missouri 63110, USA. (NW1)A

The European Molecular Biology Laboratory, an international research institute situated in Heidelberg, West Germany, invites applicants for two vacancies in the protein crystallography group headed by Dr. K.S. Wilson at the Laboratory's Outstation at the Deutsches Elektronensynchrotron (DESY) site in Hamburg

TECHNICAL ASSISTANTS

Both posts are in the protein crystallography group at the Hamburg outstation, to be headed by Dr. Keith Wilson. The assistants will be active both in the support of users at the outstation and in the scientific research or the group.

For one position a basic training in engineering or physics and for the second post experience in crystallography/biochemistry is required.

For both positions some knowledge of computer programming would be an advantage.

A working knowledge of English is essential. A second language (French or German) is desirable.

An above-average salary will be offered to the successful candidate. Certain allowances such as family, children's and non-resident allowance will be payable in addition, depending on personal circumstances.

An initial contract of 3 years' duration will be offered to the successful candidate. This can be renewed, depending on circumstances at the time of review.

Please write briefly for an application form, quoting reference N° 85/22 and 23 to:

SEARCH SCIENTISTS

Agricultural R&D

Letcombe Manor, Oxfordshire already has a track record in agricultural developments. Until recently it's been a research centre for the Agricultural Research Council. Now it's owned by the Dow Chemical Company Limited. We are investing a considerable amount in re-equipping the Manor to provide the most advanced facilities for our expanding European Agrochemical R&D operation.

Letcombe Manor gives us much needed room for growth. And as a first step we are also looking to invest in the following high calibre professionals:

R&D CHEMISTS

— to join a team undertaking work in any of the following:

- * Formulation Research & Development
- * Formulation Analysis
- * Residue and Environmental Analysis

Qualified to degree level or equivalent in Chemistry or a relevant discipline. Ref: 100.

PLANT PATHOLOGIST

— to form and lead a team involved in creating and developing both laboratory and glasshouse test procedures designed to identify new commercial fungicides.

You should have a minimum of 5 years' post doctoral experience, preferably in pesticide research. Ref: 101

BIOCHEMIST

— to join a small, innovative team researching plant pathogenic fungi.

You should be qualified to at least degree, preferably PhD level, with proven success in biochemical research. Ref: 102.

CROP PROTECTION

— Biologist or Biochemist with a good Honours degree

to the ~~Minor~~ borne

or PhD to join a team developing crop protection herbicides. Ref: 103.

REGISTRATION SPECIALIST

— for the preparation, submission and negotiation of our agrochemical product registration in Europe and Africa.

We'll be looking for someone experienced in any area of agrochemical research and with a willingness to train in registration work — ideally the person should have a degree or equivalent in chemistry or a relevant discipline. Ref: 104

In all cases we will be looking for highly self-motivated individuals with the personal and professional skills to develop their career with Dow, plus the enthusiasm, flexibility and commitment to make a

positive contribution within a small team environment.

The benefits of working for Dow go far beyond the superior facilities of our new R&D Centre. Indeed prospects for the future, in terms of our growth and your career development are excellent — there is no limit for individuals of calibre to progress. Naturally, rewards are also very generous, with competitive salaries and a wide range of fringe benefits, including generous relocation assistance where appropriate.

For more information about careers within our new Research facility, please telephone or write, quoting the appropriate reference number, to Liz Sim, Personnel Officer, Dow Chemical Co. Limited, Crossbank Road, King's Lynn, Norfolk PE30 2JD. Tel: King's Lynn (0553) 761251

CSIRO AUSTRALIA PHYTOPLANKTON ECOLOGIST

\$A26,001 — \$A38,243 p.a.
DIVISION OF FISHERIES RESEARCH
MARINE LABORATORIES
HOBART TAS

GENERAL: The Division of Fisheries Research is a major component of the CSIRO Marine Laboratories, which is Australia's principal marine research institution. The Division currently employs about 80 scientists and 55 support staff in laboratories in Hobart, Perth and Brisbane.

DUTIES: To carry out research into phytoplankton species identification and photosynthetic pigments for field programmes designed to expand the knowledge of phytoplankton in Australian waters from tropical, sub-tropical and temperate regions. Responsible for in-shore and off-shore field programmes investigating phytoplankton blooms and successions, red tides and mariculture applications.

QUALIFICATIONS: A PhD degree or equivalent qualifications preferably in phytoplankton ecology with knowledge of the phytoplankton of Australian tropical and temperate waters and skills in electron microscopy and phytoplankton pigment techniques. Ability to work effectively at sea essential.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A2361, should be directed to:

The Chief
CSIRO Division of Fisheries Research
GPO Box 1538
HOBART TAS 7001

by 2 August 1985
CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER
(W2002)A

General Anatomy

As Lecturer in the Department of General Anatomy in the School of Dentistry you will be required to teach human anatomy and human biology to dental and science students and to engage actively in research.

You should have a degree in dentistry, medicine or science, postgraduate experience being an added recommendation. Areas of research interest include developmental biology, human biology and comparative and forensic anatomy. Duties are to be assumed on 1 June 1986.

Salary: R16,257 — R27,648 per annum. **Benefits:** • pension • medical aid • annual bonus • remission of fees • generous leave • housing subsidy, travel, removal and settling-in allowances (if eligible).

It is the policy of the University not to discriminate on the grounds of sex, race, colour or national origin.

For a detailed information sheet contact:

Mr Geoff Henning, South
African Universities Office,
Chichester House, 278
High Holborn, London
WC1V 7HE, England.
Submit your application by
30 September 1985.

UNIVERSITY OF
THE WITWATERSRAND

UNIVERSITY OF SURREY DEPARTMENT OF MICROBIOLOGY POST DOCTORAL RESEARCH FELLOW

In this Department we have an active and expanding research group, under Dr J W Dale, which is applying recombinant DNA techniques to a variety of problems associated with mycobacterial diseases such as leprosy and tuberculosis. We are seeking to appoint a Research Fellow, preferably at post doctoral level or with other experience of DNA cloning. The person appointed will be responsible for a specific aspect of the project, involving the cloning and expression in *E coli* of genes for key mycobacterial antigens.

The post is available as soon as an appointment can be made, and is for two years. The starting salary will be up to £9,390 per annum according to age, experience and qualifications.

Applications in the form of a curriculum vitae (3 copies), including the names of two referees, should be sent to the Personnel Officer (JLG), University of Surrey, Guildford, Surrey, GU2 5XH by 19th July 1985 quoting reference 403. Further details can be obtained from Dr Jeremy Dale, telephone (0483) 571281 ext 871/369/N. (7001)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

DEPARTMENT OF CLINICAL TROPICAL MEDICINE MOLECULAR BIOLOGIST

This is a position funded by the Wellcome Trust for 3 years leading to a tenured post thereafter. The Wellcome position includes funding for a technician. The School has provided considerable newly-renovated and equipped laboratory space for the Department of Clinical Tropical Medicine. The present research interests in this department include the immunology of leprosy aiming towards the development of a vaccine for leprosy and a study of acute phase proteins synthesised by the liver following acute inflammatory disease. Candidates for this position must have post-doctoral experience in recombinant DNA technology and would be encouraged to pursue their own interests in addition to collaboration on current projects in the department. The new laboratories are adjacent to the Wolfson Unit of Molecular Biology with which there will be close contact.

An appointment will be made on the Universities' Lecturer or Senior Lecturer scale according to the qualifications and experience of the person appointed with membership of USS.

Candidates should send full curriculum vitae and names of three professional referees to the Personnel Officer at the London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, quoting reference CTM7. Closing date Monday 5 August 1985. (7038)A

UNIVERSITY OF BIRMINGHAM Faculty of Science DEPARTMENT OF SPACE RESEARCH

Applications are invited for a POSTDOCTORAL RESEARCH FELLOW

to undertake data analysis and interpretation of the results from the Hard X-ray Imaging Spectrometer on the Solar Maximum Mission spacecraft. Collaborative work with other data sets from this mission is encouraged.

Post is tenable for up to two years and is funded by SERC. Applicants should have a PhD in Physics or Astronomy.

Salary on the Research Fellow scale £7,520 — £12,150 plus superannuation.

For further information phone 021-472-1301, ext 2559 quoting reference E1.

No formal application form. Three copies of application, including full curriculum vitae and naming three referees to Assistant Registrar (Science) PO Box 363, Birmingham B15 2TT, by Thursday 18th July, 1985. (7016)A

UNIVERSITY OF SUSSEX School of Biological Sciences

Applications are invited for two posts funded by the MRC to work on an interdisciplinary project entitled "Influence of carboxylic acids and heavy metals on the behaviour and physiology of pulmonate snails of medical importance" under the direction of Dr J D Thomas:—

i A POST-DOCTORAL RESEARCH FELLOW (RESEARCH OFFICER IA) ii TECHNICIAN GRADE 5

Applicants should preferably have experience with HPLC, AAS, use of radiolabel and toxicity testing.

The posts are tenable to the end of March 1986 in the first instance, and are to commence as soon as possible. Salaries on the Research Officer IA scale: £7,520 to £9,860. ii Technician Grade 5 scale: £6,581 to £7,011.

Two copies of the application, including full curriculum vitae and the names of three referees should be sent to Dr J D Thomas, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG. (7003)A

THE UNIVERSITY OF PAPUA NEW GUINEA

Port Moresby

LECTURER/SENIOR LECTURER IN ENVIRONMENTAL AND ANALYTICAL CHEMISTRY — PO31006/85

The Chemistry Department has a vacancy from the beginning of 1986 in the field of Environmental and Analytical Chemistry. The appointee will be required to teach a final year course in Environmental Chemistry, a more general course in Analytical Chemistry and contribute to basic and honours level courses. Applicants should have research skills which will allow involvement with research programmes in inland water quality and coastal water quality sponsored by the South Pacific Regional Environmental Programme.

The appointment will be for two years, with a possible extension for one further year overlapping with a national member of staff who will return from training overseas in early 1988. The University welcomes applications from persons who would be on secondment from a permanent position.

SALARY: Senior Lecturer K21255, Lecturer Grade 2 K19405, Lecturer Grade 1 K17555 per annum plus gratuity.

OTHER CONDITIONS: The gratuity entitlement is based on 24% of salary earned and is payable in instalments or lump sum and is taxed at a flat rate of 2%. In addition to the salaries quoted above, the main benefits include: support for approved research; rent-free accommodation; appointment and repatriation airfares for appointee and dependants; financial assistance towards the cost of transporting personal effects to and from Papua New Guinea; 6 weeks annual recreation leave with home airfares available after each 18 months of continuous service; generous education subsidies for children attending schools in PNG and overseas; a salary continuation scheme to cover extended illness or disability. The terms and conditions are under review.

Applications will be treated as strictly confidential and should include a full curriculum vitae, a recent photograph and the names and addresses of three referees. In order to expedite the appointment procedure, applicants are advised to ask their referees to send confidential reports directly to the University without waiting to be contacted. Applications should be forwarded to the Deputy Registrar (Staffing), University of Papua New Guinea, PO Box 320, University Post Office, Papua New Guinea. Applications close on 31 August 1985. Candidates in UK should also send a copy of their application to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1987)A

THE ANIMAL AND GRASSLAND RESEARCH INSTITUTE A BIOCHEMIST

Is required at Shinfield, Reading, to join a team investigating the hormonal control of intermediary metabolism and nutrient partitioning in ruminants. Current interest is focussed on the use of naturally occurring and modified forms of bovine growth hormone to stimulate milk yield in dairy cows and body growth in lambs. Facilities are available for whole animal studies using isotope dilution techniques, colorimetry, metabolite analysis and radioimmunoassay and also for in vitro tissue culture and bioassay.

A suitable candidate will have a First or Upper Second Honours Degree in Biochemistry, with at least four years relevant postgraduate experience and preferably a PhD. Candidates with interests in animal production and/or endocrinology will be preferred.

The appointment will be on the Senior Scientific Officer scale £9,772 to £12,653.

Application forms from the Personnel Officer, Animal & Grassland Research Institute, Hurley, Maidenhead, Berks, SL6 5LR, to be returned by 18 July 1985 quoting S/D/49. (7040)A

UNIVERSITY OF CAMBRIDGE UNIVERSITY LECTURERS AND UNIVERSITY DEMONSTRATORS

in the Department of Anatomy
(four posts)

Applications are invited for four posts of University Lecturer or University Demonstrator (the equivalent of University Assistant Lecturer); not more than two of these posts will be filled at the Lecturer level. Appointment will commence on 1 December 1985, or as soon thereafter as possible. Candidates should be graduates in Medicine or Science and will be required to teach and to contribute to research, for which there are excellent facilities. The teaching and research of the department covers a wide field including topographical and functional anatomy, neuroscience, developmental biology and cell biology. The Department seeks a person with a particular interest in developmental or cell biology to fill one post.

Stipends: University Lecturer £10,330 (by eleven increments) to £15,930. University Demonstrator, £7,980 (by four increments) to £9,860.

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee for the Faculty of Biology 'B', 19 Trumpington Street, Cambridge, CB2 1QA, to whom applications (10 copies) including a curriculum vitae, list of publications and the names of not more than three referees, should be sent so as to reach him not later than 13 September 1985. (6997)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY CENTRE FOR BIOTECHNOLOGY

Research Staff

A new building has been provided for the Centre for Biotechnology at Imperial College, which links the biochemistry and chemistry departments, and which is immediately adjacent to the Fermentation Plant of Imperial Biotechnology Ltd. The Centre is now able to recruit staff in support of work in the general area of Chemical Transformations by Micro-Organisms. Applications are invited for the following posts:

Research Officer in Microbial Chemistry (Ref: ROMC)

This is an SERC funded post-doctoral position available in the first instance for two years, to continue an NMR study of the microbial transformations of aromatic compounds. Preference will be given to applicants with a degree in chemistry, experience in NMR experiments and the interest to monitor in vivo metabolic and physiological events: It is anticipated that H, C, F and P will be the principal nuclei monitored. The work envisaged is in collaboration with Professor D.W. Ribbons and Dr A.E.G. Cass. This position is available from October 1985, but a later starting date will be considered for well-qualified and motivated individuals. Salary in the academic-related scale 1A £8,753 — £13,383 including London Allowance + USS.

Serc Studentship (Ref: SQUO)

SERC have provided a quota studentship to the Centre for Biotechnology at Imperial College for research leading to a Ph.D. degree. Applications are invited from persons with honours degrees (at least Upper Seconds) in chemistry, biochemistry, microbiology or related subjects, to initiate a programme of research on the Microbial Transformations of Alkenes with a view to the Generation of Chiral Intermediates for Chemical Synthesis, and a fundamental study of Enzymic Oxygenative Processes. The work will be supervised by Dr D.J. Leak.

SERC Studentship (Ref: SB10)

A Studentship provided by the Biotechnology Directorate of SERC is available for a research project leading to a Ph.D. degree on the generation of novel microbial metabolites which are seen as useful intermediates in chemical synthesis of polymers, fused ring systems and complex natural products. The work is to be supervised by Professor D.W. Ribbons, Dr D.J. Leak (Biotechnology) and Professor S.V. Ley (Organic Chemistry). Candidates should have at least an Upper Second Class honours degree in Chemistry (preferable) or Biochemistry or Microbiology.

Research Studentship (Ref: Biolum)

An industrially funded Research Studentship is available to work in the Biosensors Group at the Centre. The project involves the development of bioluminescence systems for ultra-trace analysis; this work is being carried out in collaboration with the Department of Electrical Engineering. Candidates with an honours degree in either chemistry or biochemistry are invited to apply.

Applications should be sent to Professor D.W. Ribbons, Centre for Biotechnology, Imperial College of Science and Technology, South Kensington, London SW7 2AZ by July 15, 1985, and these should include a curriculum vitae and the names of three referees. (7046)A

ASSISTANT OR ASSOCIATE PROFESSOR (Molecular and Cell Biology)

The Biology Programs of The University of Texas at Dallas invite applications for two tenure-track positions, one at the Assistant Professor level and one at the Assistant or Associate Professor level, beginning 1 September 1986. While the area of specialization is open, applicants should be actively engaged in research in the broad area of molecular or cellular biology, have at least two years postdoctoral experience and show evidence of independent, productive work sufficient to compete for federal grant support. The University has a small (60 majors) upper-level undergraduate biology program and a graduate (60 M.S./Ph.D.) biology program, with extensive extramural supported research in molecular and cellular biology. Successful candidates will be expected to participate in teaching of molecular biology (in biochemistry/biophysics OR molecular genetics), supervise graduate student research, develop a vigorous and independent research program and interact with the current faculty.

Send a curriculum vitae (indication of sex and ethnicity for Affirmative Action statistical purposes is requested but not required), a short description of research plans and names of three or more references to:

Academic Search #271
The University of Texas at Dallas
P.O. Box 830688
Richardson, Texas 75083-0688

Applications should be received by October 15, 1985.

The University of Texas at Dallas is an Affirmative Action/Equal Opportunity Employer. (NW2)A

LOUGHBOROUGH
UNIVERSITY
OF TECHNOLOGY

RESEARCH POSTS IN CHEMICAL ENGINEERING

Several opportunities are available at various levels for work on the following topics.

1. Post-Doctoral

"Characterisation of novel commercial semi-porous membranes for reverse osmosis and ultrafiltration".

2. Research Assistants

- (a) "Hazardous zone definitions in plant layout"
- (b) "Solids control in drilling muds used in oil field operations"
- (c) "On-line monitoring of particulates in fluids used for semi-conductor manufacture"
- (d) "Design of process systems to produce ultra clean fluids for use in semiconductor production"

3. Research Studentships

- (a) "Process Computer Alarm Systems" funded by SERC-BP.
- (b) An SERC studentship is also available for a candidate to work on a mutually agreed topic.

Candidates for Post 1 should have a Ph.D. Starting salary will be not less than £7,520.

For posts 2 and 3 candidates should have a good honours degree in chemical engineering or a related discipline and can register for a higher degree.

Salaries for posts 2, not less than £6,600. Studentship grant is currently £2,585 minimum plus fees.

Write or telephone Dr. A.S. Ward, Department of Chemical Engineering, University of Technology, Loughborough, Leics. LE11 3TU. Tel: 0509 263171 extn. 5033. (7007)A

L'UNIVERSITE DE LAUSANNE

ouvre une inscription en vue de pourvoir, dès le 1er septembre 1986, un poste de

PROFESSOR ASSOCIE

rattaché à l'Institut de Zoologie et d'Ecologie animale (IZEA) de la Faculté des sciences.

Il s'agit d'un poste à plein temps, comportant de l'enseignement (écologie quantitative, génétique des populations et spéciations) et de la recherche (relations phylétiques et écologie des mammifères).

Les candidatures (curriculum vitae, liste des publications, tirés à part des publications les plus significatives) doivent parvenir avant le 30 septembre 1985 au professeur Bernard TESTA, doyen de la Faculté des sciences, Collège propédeutique, 1015 Lausanne-Suisse. (W1993)A

CHAIRMAN — DEPARTMENT OF PHYSIOLOGY

University of Colorado Health Sciences Center seeks a chairperson for the Department of Physiology. Those interested should contact: John V. Weil, M.D., Chairman, Physiology Search Committee, University of Colorado Health Sciences Center, 4200 E. Ninth Ave., Campus Box B-133, Denver, CO 80262. AA/EEO. (NW8)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY RESEARCH ASSISTANT

to work on biophysical and biochemical studies of the cardiac sarcoplasmic reticulum. Applicants should have a PhD in biochemistry and preferably experience in either working with biological membranes or in the area of phosphorylation-mediated control of enzyme activity. Experience in the use of physical techniques in biology an advantage but not essential.

The post is for approximately 2 years, supported by a grant from the British Heart Foundation to Professor D Chapman.

Full curriculum vitae and the names and addresses of two referees should be sent to School Office, RFHSM, Rowland Hill Street, London NW3 2PF (794-0500 Extn 4262). Please quote reference DC/RA. Closing date 19 July 1985. (7033)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS Centre for Applied
Microbiology & Research

THERAPEUTIC PRODUCTS
LABORATORY

PROCESS DEVELOPMENT BIOCHEMIST

A protein chemist/enzymologist is required for the development of purification processes and characterisation of new therapeutic products from human pituitary glands and recombinant DNA technology using pharmaceutically acceptable techniques. The work will include research into methods of protein immobilisation for immunoaffinity chromatography and the development of tests to assess the safety of parenteral products derived from cloned or fused cell lines.

Applicants should possess a good Honours Degree in Biochemistry/Chemistry and at least three years relevant post graduate experience. Further information may be obtained from Dr G W Jack, Head of Process Development Section, TPL.

The successful applicant will be appointed as a Basic Grade Microbiologist.

Salary will be in the range £6,559 — £8,725.

National Health Service terms and conditions will apply.

Applications including curriculum vitae and the names and addresses of three referees should be sent to the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wiltshire SP4 0JG.

The closing date for applications is 29 July 1985.

Please quote Reference 29 when applying. (6995)A

THE UNIVERSITY OF THE SOUTH PACIFIC Suva, Fiji

Applications are invited for the following position:

LECTURER I/ SENIOR LECTURER IN CHEMISTRY — POST 85/37

Applicants should have a proven record of teaching and research in analytical, inorganic or physical chemistry and some experience in administration will be an advantage. Competence at teaching all the main areas of analytical, inorganic or physical chemistry to general degree level will be required. Staff are expected to supervise postgraduate students for higher degrees and may be involved in teaching courses through extension and in consultancy projects for associated University Institutes. The successful applicant is expected to take up the position on January 1, 1986 or as soon as possible after that date. Appointment will be for a contract period of three years and may be renewable by mutual agreement.

Salary scales: Lecturer I F\$13,921 — 18,919, Senior Lecturer F\$19,525 — 22,815 (£1 = F\$1.49 on 11-6-85). Salary will be in accordance with qualifications and experience.

In addition, the University provides gratuity amounting to 15% of basic salary, appointment allowance and, subject to the University's current housing policy, partly furnished accommodation at a rental of 12½% of salary. The University will contribute a sum equivalent to 10% of the appointee's salary towards his superannuation obligations. Candidates should send three copies of their curriculum vitae with full personal particulars, names and addresses of three referees and date of availability, to the Registrar, University of the South Pacific, PO Box 1168, Suva, Fiji, to reach him no later than 3 August 1985.

Further information on request from the Registrar or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, to whom candidates in-UK should also send an additional copy of their applications. (W1997)A

POSTDOCTORAL POSITION

Position available to study the biochemistry, immunology and genetics of a human malaria parasite. Duration — two years — starting as soon as possible. Experience in biochemistry, immunochemistry or recombinant DNA techniques desirable.

Send CV and the names of three referees to: Dr Joseph Inselburg, Department of Microbiology, Dartmouth Medical School, Hanover, NH 03756, (603) 646-7666.

Dartmouth College is an affirmative action employer. (NW9)A

**THE ANIMAL VIRUS
RESEARCH INSTITUTE**
Ash Road, Pirbright, Woking,
Surrey GU24 0NF
**HIGHER SCIENTIFIC
OFFICER**

Following the restructuring of the Animal Virus Research Institute, applications are invited for a new post of Higher Scientific Officer to work in the Division of Molecular Biology, Director's Group. The appointment to commence as soon as possible. The successful candidate will work on the mechanisms of replication of fowl plague virus RNA.

Candidates should have a First or Upper Second Class Honours degree with at least two years post graduate qualifying relevant research experience.

Salary scale £7,788 — £10,541, sick leave and non-contributory superannuation schemes, 22 days annual holiday. House may be available for suitable married applicant.

Applications to include a curriculum vitae and the names of two referees should be sent as soon as possible to: The Secretary, The Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey GU24 0NF. Tel: 0483 232441/8.

The Animals Virus Research Institute is an Equal Opportunities Employer. (6945)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
**POST-DOCTORAL
RESEARCH ASSISTANT**

Applications are invited for the above SERC-funded position which forms part of a small group studying the mechanism of cofactor acquisition by molybdoenzymes in *E. coli*. The project involves the biochemical analysis of a series of mutants which are defective in molybdoenzyme biosynthesis. Enzymological and molecular genetic approaches are being employed. Persons with experience in either or both of these areas are preferred but other strong applicants will also be considered. Further information may be obtained from Dr D H Boxer (0382 23181, ext 4250). The position is available for up to three years starting on 1 October 1985.

Appointment will be on the Research & Analogous IA scale currently £7,520 — £12,150 depending on qualifications and experience.

RESEARCH STUDENTSHIP

A SERC Studentship awarded specifically for the above project is also available. The project could either centre on the molecular genetic or enzymological aspects of the work. Applicants for this position should apply as below but directly to Dr Boxer.

Please apply enclosing a curriculum vitae and the names of two referees to The Personnel Officer, The University, Dundee, DD1 4HN by 25th July 1985. Please quote REF EST/75/85J. (7000)A

**UNIVERSITY OF
AUCKLAND**
New Zealand
**LECTURESHIP IN
GEOCHEMISTRY**
(3 year term)

Closing date: 17 August 1985

Applicants should have advanced qualifications and have teaching and research experience and interests in fluid geochemistry and physical chemistry, and preferably have experience with the geochemistry of geothermal fluids. The successful applicant will be required to teach, supervise laboratories and conduct research within the Geothermal Institute and Department of Geology.

Commencing salaries will be established within the appropriate scale: Lecturers NZ\$23,622 — \$27,928, Senior Lecturers NZ\$29,430 — \$37,240.

Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand, or the Secretary General, Association of Commonwealth Universities (Appts), 26 Gordon Square, London WC1H 0PF. Applications, in accordance with the Method of Application should be forwarded as soon as possible, but not later than the closing dates stated. (W1998)A

**THE INSTITUTE OF
CANCER RESEARCH:**
**TECHNICIAN/RESEARCH
OFFICER**

is required to continue an established project funded by the CRC/MRC at the Institute's laboratories at Sutton, Surrey. The project involves the use of mouse aggregation chimaeras. These are produced by combining embryos from two different mouse strains: the tissues of resulting progeny are a mosaic of cells of each parental type, which can be stained immunohistochemically. The mosaicism is being used to examine clonal organisation and interaction in normal and neoplastic tissue. Training is available in a wide range of techniques relevant to the project: but experience of histology would be an advantage. Post available now: starting date to be arranged.

Salary in the range of £5,738 — £8,492 + £623 pa. London Weighting allowance.

Applicants are advised that in the majority of the Institute's premises smoking is prohibited.

Prospective applicants are encouraged to telephone Dr Bruce Ponder on 01-643 8901 Ext 293 for further details.

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference 301/B/83. (7008)A

Marine Laboratory, Aberdeen
**Department of Agriculture
and Fisheries for Scotland**

Chemist

To join a group investigating the sources, distribution, fate and controlling processes of trace metals in the marine environment. You will participate in laboratory and field investigations including research cruises and you will be expected to adopt a multi-disciplinary approach to these studies and to be capable of innovative and unsupervised work.

You should have a degree, HND, HNC or equivalent in chemistry, chemical oceanography or other relevant scientific subject. Postgraduate experience in marine chemistry or chemical oceanography would be advantageous.

Appointment will be as Scientific Officer £6190-£8560 with starting salary according to qualifications and experience. Ref: SA/35/DLC.

Physical Oceanographer

To join a group involved in oceanographic research programmes related to environmental problems of fishery management and the impact of pollution on marine life.

You should have a 1st or 2nd class honours degree in physics or a relevant subject with at least 2 years' postgraduate experience in physical oceanography. A knowledge of the skills needed to make full use of oceanographic instrumentation and computer facilities would be an advantage.

Appointment will be as Higher Scientific Officer £7785-£10,540 or Senior Scientific Officer £9770-£12,650 with starting salary according to qualifications and experience. Ref: SA/36/DLC.

For further details and an application form (to be returned by 26 July 1985) write to Scottish Office, Personnel Division, Room 208, 16 Waterloo Place, Edinburgh EH1 3DN.

Please quote appropriate reference.

The Civil Service is an equal opportunity employer

(7044)A

**Scientific
Civil Service**

**CROP PHYSIOLOGIST/
POMOLOGIST**

The Department of Pomology, University of California, Davis, invites applications to fill a tenure track position as Assistant Professor and Assistant Pomologist (10% teaching/90% research). The appointee will be expected to conduct research related to soil-plant-water relationships and irrigation strategies for deciduous fruit and nut crops. Potential research projects include, but are not limited to, the effects of soil moisture and plant water status on tree growth, root behaviour, crop yield and quality, and predisposition of deciduous fruit trees to pests and diseases. Interaction with Cooperative Extension personnel and participation in student advising and upper division and/or graduate pomology courses will be expected. A Ph.D. degree in plant physiology, pomology, botany, or a related field is required. Previous experience with tree crops is desirable but not prerequisite.

Submit curriculum vitae, official undergraduate and graduate transcripts, publications list, reprints, statement of research and teaching interests, and names and addresses of at least three referees to: Ted M. DeJong, Search Committee Chairperson, Department of Pomology, University of California, Davis, CA 95616 prior to October 1, 1985.

The position will be available for appointment December 1, 1985, or later depending on availability of the successful applicant.

In conformance with application law and University policy, the University of California is an Affirmative Action/Equal Opportunity Employer. (NW6)A

CARCINOGENESIS

The University of Texas System Cancer Center (UTSCC)

Science Park-Research Division

Applications are invited for an assistant professor level faculty position in a multidisciplinary research laboratory studying cellular and molecular mechanisms of carcinogenesis. Research programs at Science Park, located in Buescher State Park 40 miles east of Austin, include somatic cell genetics, DNA repair and mutagenesis, carcinogen metabolism and adduct formation, tumor promotion, mechanisms of lymphomagenesis, normal and tumor cell differentiation, biochemical genetics, and growth factors. Candidates should have an independent research program that would interface with one or more of the above areas as well as a record of peer-reviewed grants and research publications. Preference will be given to individuals who have an active program on the cellular and molecular mechanism(s) by which dietary fat influences the induction of cancer in the mammary gland, large bowel, or pancreas. The Science Park provides competitive salary and benefits, a stimulating research environment, postdoctoral and graduate students, and opportunities for interaction with faculty at nearby institutions, including the University of Texas Health Science Center in Houston, University of Texas at Austin, and Texas A&M University.

Interested applicants should send complete curriculum vitae, the names of three referees, and a brief statement of research interests to: Dr Thomas J. Slaga, Director, UTSCC, Science Park-Research Division, P.O. Box 389, Smithville, Tex. 78957; Telephone: 512-237-2483.

An Equal Opportunity/Affirmative Action Employer.

(NW5)A

LIFE SCIENCE RESEARCH ASSISTANT: REQUIRE Ms IN CHEMISTRY

1-3 years experience in separation of macromolecules using gel chromatography and HPLC. Ability to set up HPLC and interface the instrument with computer required. Experience in microanalysis by immunodiffusion and knowledge of osmometer, creatinine analyzer, autoanalyzer, oncometer and fractionator necessary. Knowledge of polymer and protein chemistry desirable. 1844-2331/month.

Closing date August 4, 1985. Send résumé to: Carol Young, S215, Stanford Medical Center, Stanford, CA 94305.

(NW4)A

RESEARCH TRAINING IN SALIVARY SECRETION

Positions available starting summer 1985 at the University of Washington for research training in the biochemistry, cell biology, microbiology, physiology, pharmacology and/or pathology of salivary secretion. Applicants should have Ph.D. or professional degree (M.D., D.D.S., D.V.M., or equivalent) and must be U.S. citizens or have permanent visas.

Graduate programs leading to Ph.D. or M.S. are available. Stipends: \$15,996 to \$30,000, depending upon exercise.

Send curriculum vitae, three references and statement of research interests to: Dr Kenneth Isutsu, Department of Oral Biology, SB-22, University of Washington, Seattle, Wash. 98195 at earliest possible date.

An Affirmative Action Equal Opportunity Employer.

(NW7)A

UNIVERSITY OF ST ANDREWS MRC Cognitive Neuroscience Research Group POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post to work on an MRC funded project investigating the behavioural and neurological sequelae of closed head injury. The project involves the employment of psychometric and neuropsychological testing procedures, and the collection of scalp-recorded evoked potentials in a range of paradigms. Applicants should be familiar with at least some of these techniques, and should possess a valid driving licence.

The appointment will be for 31 months, starting salary near the bottom of the 1A scale (1st point £7,520). Further details of the post are available from Dr M D Rugg, Department of Psychology, University of St Andrews. Applications (two copies preferably in typescript) with the names of two referees should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ, to arrive not later than 24 July 1985.

(7028)A

THE UNIVERSITY OF WALES ABERYSTWYTH DEPARTMENT OF AGRICULTURE RESEARCH OFFICERS

Applications are invited for two MAFF funded posts tenable for a period of three years commencing 1 August 1985, or as soon as possible thereafter, to investigate the Nitrogen Cycle on Organic Farms.

One post will concentrate on monitoring the Nitrogen cycle on a whole farm and individual field basis and the other on studying the availability of Nitrogen from the soil. Salary within the range £6,600 to £7,520 per annum.

Application forms and further particulars can be obtained from the Staffing Officer, The University College of Wales, Old College, King Street, Abersystwyth, SY23 2AX (Tel 0970 3177, Ext 207). Closing date for applications: Friday, 19 July 1985.

(7050)A

UNIVERSITY OF AUCKLAND New Zealand CHAIR IN NEUROPHYSIOLOGY (DEPARTMENT OF PHYSIOLOGY — SCHOOL OF MEDICINE) CLOSING DATE: 13 SEPTEMBER 1985

This is a newly established Chair open to both medically and non-medically qualified applicants. Medical qualifications must be registrable in New Zealand. The Chair has been established with a view to promoting interdisciplinary graduate studies in the neurosciences. Applicants should have postgraduate qualifications in an appropriate field and an established record of research achievement in neurophysiology. Teaching experience at both undergraduate and graduate levels is essential, and the successful applicant will be expected to promote the development of a Centre for Graduate Studies in Neural Sciences. Commencing salaries will be established within the ranges NZ\$58,174 — \$64,121 per annum for medically qualified, or NZ\$45,319 — \$56,602 for non-medically qualified applicants, having regard to the qualifications of the candidates concerned.

CHAIR IN RADIOLOGY (DEPARTMENT OF ANATOMY — SCHOOL OF MEDICINE) CLOSING DATE: 20 SEPTEMBER 1985

Applications are invited from persons with medical qualifications registrable in New Zealand, and with a higher postgraduate qualification in Radiology. The successful applicant will be expected to organise and assist with both undergraduate and postgraduate teaching in radiology in the School of Medicine and Auckland Hospital, to control the experimental radiological laboratory within the School of Medicine and to engage in, encourage and supervise research. Commencing salaries will be established within the range NZ\$58,174 — \$64,121 per annum, having regard to the qualifications of the candidates concerned.

Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, New Zealand, or from the Secretary General, Association of Commonwealth Universities (appts), 36 Gordon Square, London WC1H 0PF. Applications, in accordance with the Method of Application, should be forwarded as soon as possible but not later than the closing dates states.

(W1986)A

CSIRO

AUSTRALIA RESEARCH LEADER (IMMUNOLOGY) \$39,692 — \$52,212 AUSTRALIAN NATIONAL ANIMAL HEALTH LABORATORY GEELONG VIC

The Australian National Animal Health Laboratory (ANAH) is a high security microbiological laboratory for the study of animal diseases exotic to Australia. It is located at Geelong, a city with a population of 170,000 situated 80 kms south of Melbourne. When fully operational in 1985/86 it will employ a staff of 178, including 30 scientists.

ANAH has a most important role in the diagnosis and control of exotic diseases of livestock in Australia. To carry out its role it undertakes disease diagnosis, research, development and testing of vaccines, and training of field and laboratory personnel. These functions support and complement those undertaken by the various disease control authorities in Australia.

Currently there are four research groups in ANAH — Epidemiology, Molecular Virology, Pathogenesis and Immunity, and Microbiological Security with expertise in microbiology, immunology, veterinary pathology and molecular biology. Facilities are available within the Laboratory for gene cloning and sequencing, protein synthesis and sequencing, electron microscopy, histopathology and immunology. The Laboratory is currently seeking to appoint a co-ordinator for its Pathogenesis and Immunity Group. The appointee will establish the group and lead research into the pathogenesis and immunity of virus diseases of livestock.

Applications are invited from persons with a PhD or equivalent degree in a relevant field, plus a record of extensive research achievement in the field of viral immunology. Evidence of scientific leadership would be an advantage. Appointment to CSIRO is for an indefinite period and carries Australian Government superannuation benefits, subject to normal conditions. The position of Group Co-ordinator however will be offered for a negotiable term, in the order of three to five years, with subsequent options for a further term if mutually desired.

Enquiries or applications stating relevant personal and professional details, the names of at least three referees, and quoting reference Nc A6877 should be directed to: Mr V. A. Snowdon, Chief, CSIRO Australian National Animal Health Laboratory, PO Bag 24, GEELONG VIC 3220, 26 July 1985.

DEPARTMENT OF BOTANY AND
MICROBIOLOGY
**POST-DOCTORAL
RESEARCH ASSOCIATE**

Applications are invited from Plant Physiologists, Plant Biochemists or Natural Products Chemists, to join a research group supported by an AFRC special block grant working on the biochemistry of endogenous plant growth regulators. The current research interests of the group include the biosynthesis and metabolism of cytokinins and the pathway and control of abscisic acid biosynthesis in plants. The appointment will be for an initial period of 18 months within the salary range £7,520 to £8,450 per annum.

Application forms and further particulars can be obtained from the Staffing Officer, The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX (Tel 0970 3177, Ext 207). Informal enquiries can be made to Dr Roger Horgan (Tel 0970 3111, Ext 3054). Closing date for applications: Friday, 26 July 1985. (7051)A

**THE UNITED MEDICAL
AND DENTAL SCHOOLS**

St Thomas's Campus

RESEARCH ASSISTANT
(possibly post-doctoral)

required to work on immunity to and the molecular biology of rubella virus. Virology experience essential; some knowledge of ELISA and PAGE techniques and use of monoclonal antibodies an advantage.

Funding for post is currently being sought; anticipated start date early September.

Salary according to age and experience.

Applications with cv and names and addresses of two referees to Staffing Officer, Dean's Office, St Thomas's Hospital Medical School, London SE1 7EH, not later than 18th July, 1985 quoting ref: STH/V/38. (6859)A

**BEN GURION UNIVERSITY
OF THE NEGEV
BEER SHEVA — ISRAEL**

DEPARTMENT OF BIOLOGY

Two tenure-track academic positions are available in the Department of Biology, for scientists working at the molecular or organismic level in modern fields of biology. Teaching responsibilities include undergraduate and graduate courses. The level of appointment is dependent upon the academic achievements and experience of the candidate.

Applications including CV, list of publications, description of areas of research interests and names and addresses of at least three referees should be sent to Prof Chanan Itai, Chairman, Department of Biology, Ben Gurion University of the Negev, Beer Sheva, Israel. (W1988)A

**UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
ORGANELLE DIVISION
DURING MITOSIS**

A post-doctoral research assistant is required to work on the division of the Golgi complex during mitosis in animal cells. The aim is to understand the molecular basis of this process. Preference will be given to candidates with training in membrane biochemistry and/or enzymology.

This project is funded by the CRC and the position is for three years commencing 1 October 1985. Salary will be in the range £7,520 — £12,150 per annum.

Applications, including a curriculum vitae, research summary and the names and addresses of three referees, should be sent to the Personnel Officer, University of Dundee, Dundee DD1 4HN, Scotland as soon as possible. Informal enquiries concerning this project should be addressed to Professor Graham Warren, who is presently at the European Molecular Biology Laboratory, Postfach 10.2209, 6900 Heidelberg, West Germany, telephone number 010 49 6221 387 324. In the Physiology Unit

**CARDIORESPIRATORY
PHYSIOLOGIST**

As part of an integrated approach to the physiological and biochemical response of the racehorse to exercise, an experienced cardiorespiratory physiologist is required to join a team of veterinarians and biochemists. The response of animals exercised on the track, as well as in a newly built Exercise Unit containing a high speed treadmill and other facilities will be investigated. Emphasis will be on pulmonary function and gas exchange, with studies to be undertaken in both normal horses and those with respiratory disorders. Some comparative studies in other species will be undertaken. The work will also be part of a collaborative project with the Department of Zoology and Comparative Physiology, University of Birmingham.

The Fellowship will be for 4 years. Salary range £8,920 — £10,720.

For further details contact Dr D H Snow. Application forms available from the Administration Secretary, to be returned to The Director, The Animal Health Trust, Balaton Lodge, Snailwell Road, Newmarket, Suffolk CB8 7DW (Tel: 0638-661111). Closing date: 16th August 1985. (7053)A

CSIRO

AUSTRALIA

RESEARCH FELLOW

\$26,001 — \$38,243

DIVISION OF SOILS

ADELAIDE SA

FIELD: Plant physiology/biophysics.

GENERAL: The CSIRO Division of Soils conducts research into most aspects of soil science, including the physics, chemistry and biology of soils, and the integrative disciplines of pedology and geomorphology. It also seeks the application of its research in agriculture and other areas of science and technology. The Division has laboratories in Adelaide, Brisbane, Canberra and Townsville.

DUTIES: The appointee will undertake research on the movement of water both to and from plants. Initially, the research will evaluate the usefulness of the natural isotopes deuterium and oxygen-18 to elucidate details of the mechanism of water loss from plants.

The appointee will be based at the Division's Adelaide Laboratory which is equipped with a VG602 mass spectrometer and extensive growth cabinet and glasshouse facilities.

QUALIFICATIONS: Applicants should have a PhD degree or equivalent qualifications with training in some aspects of plant science. Some knowledge of physics would be an advantage.

TENURE: A term of 3 years. Australian Government superannuation benefits are available.

APPLICATIONS: Stating relevant personal and professional details, the names of at least two scientific referees and quoting reference No A0997 should be directed to:

The Chief
CSIRO Division of Soils
Private Bag No 2
GLEN OSMOND SA 5064

by 26 July 1985
CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER
(W2006)A

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMISTRY

Applications are invited from Chemistry graduates, or those about to graduate, for the following research studentships which will become available as from 1st October, 1985.

1) A CASE studentship in conjunction with ICI Pharmaceuticals to study

A Thermodynamically-Based
Scale of Hydrogen Bond
Basicities

(Dr M H Abraham)

2) A CASE studentship in conjunction with the Imperial Cancer Research Fund to study

Mechanisms of Aromatic
Hydroxylations

(Dr J R Jones)

3) A CASE studentship in conjunction with ICI to study

The Synthesis of Polysulphones
from Arylsulphonic
Acids and PC1 25 3

(Professor J B Rose)

Interested persons should send their curriculum vitae and the names and addresses of two referees to Dr J R Jones, Chemistry Department, University of Surrey, Guildford, GU2 5XH, as soon as possible. (7037)A

**AGRONOMIST
Bedfordshire**

Our Client is an international leader in plant breeding and seed marketing. An Agronomist is required to set up and develop field trials in the U.K.

Applicants must have 1 or 11 Hons. in Agricultural Sciences or Botany with Agriculture. Relevant experience would be beneficial. Essential is a long term commitment to agronomy, an understanding of farming requirements and the ability to record and interpret trial data. A practical approach together with physical fitness is even more important since considerable planting of crops is involved in several locations.

This is an exceptional career opportunity with management potential for those with the appropriate commitment to commercial seed development.

Attractive salary, according to experience. Starting date: August/September 1985. A driving licence is essential.

Contact R.G. Bubb, Director with C.V. or send for application form and further details to DSA Appointments, Flitch House, 42 High Street, Great Dunmow, Essex. CA6 1AH. Telephone (0371) 5106. (7020)A

HIGH MODULAS POLYMERS

ULIS (University of Leeds Industrial Services) Ltd., wishes to make contact with an experienced

RESEARCH WORKER

to develop applications for high modulus polymers, a field in which there is a very active programme of research at Leeds University. The post, which is for two years in the first instance, could be filled by a graduate/post graduate in physics, chemistry engineering or materials science

Salary according to age and qualifications in the range £6,600 — £8,920/£7,250 — £12,150.

Please send C.V. and full details with 2 referees to M.D., ULIS Ltd. 175 Woodhouse Lane, Leeds 2, marking envelope "Confidential". (7017)A

UNIVERSITY OF WISCONSIN-MADISON Mycology/Microbial Ecology RESEARCH ASSOCIATE (postdoctoral)

position available 1 June 1985 on the BIOTECHNOLOGY and microbial ecology of fungal pathogens (biocontrols) to watermillfoil. Research aspects include mass culture and strain improvement techniques, interaction with other control measures, and tracking marked populations in water and sediment. Funding for two years. Salary competitive and commensurate with qualifications.

Send résumé with names of 3 referees to: Dr. John H. Andrews, Department of Plant Pathology, 1630 Linden Drive, Madison, WI 53706.

An affirmative action/equal opportunity employer. (NW1914)A

POSTDOCTORAL FELLOW

The Center for Separation Science, College of Engineering, and the Department of Pharmacology, College of Medicine, have a joint full-time position available to study neuropeptide processing (metabolism) in animal tissues. The focus of the studies is applying state-of-the-art separation techniques to the isolation and purification of peptide specific proteolytic enzymes altered by disease or drugs. A strong background in biochemistry and pharmacology desired.

Applications will be accepted until August 15, 1985.

Salary: £18,000.

Send résumé, copies of representative publications, and names of three referees to: Dr. Thomas P. Davis, Department of Pharmacology, University of Arizona, College of Medicine, Tucson, Arizona 85724.

Equal Opportunity/Affirmative Action Employer. (NW3)A

HOUGHTON POULTRY RESEARCH STATION Grant-Aided by the Agricultural & Food Research Council TEMPORARY MOLECULAR BIOLOGIST

Applications are invited for the above post to work on molecular aspects of pathogenesis of Marek's disease. Areas of interest are in situ hybridization and characterization of RNA transcripts and their translated products in infected cells.

Candidates should have recently completed a PhD degree or be graduates with experience in molecular biology of nucleic acids. A background in virology would be an advantage but is not essential.

The post is for a period of 2 years and is supported by the Leukaemia Research Fund. Informal enquiries to Dr N Ross (Tel 0480-64101).

The appointment will be made to the Higher Scientific Officer grade (salary £7,788 × 6 — £10,541) or the Senior Scientific Officer grade (salary £9,772 × 7 — £12,653) depending on experience and qualification.

An application form and further particulars may be obtained from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs. The closing date for applications is 25th July 1985. (6972)A

PUBLIC HEALTH LABORATORY SERVICE BOARD Central Public Health Laboratory PRINCIPAL MICROBIOLOGIST Antibiotic Reference Laboratory Division of Hospital Infection

The post is associated with the establishment of an Antibiotic Reference Laboratory by the PHLS Board. The Principal Microbiologist will be expected to play a large part in developing and expanding the work of the new laboratory; in particular the study of the genetics and mechanisms of antibiotic resistance.

Candidates should have a first degree in Microbiology or a related subject, and post graduate experience is essential.

This is a permanent post, salary on the scale £11,927 to £16,730 plus £648 per annum London Weighting NHS terms and conditions of service will apply.

The department may be visited by arrangement with Dr R C George (Telephone 01-200 4400, extension 4222).

Application forms and job description are available from the Personnel Officer, Public Health Laboratory Service Headquarters, 61 Colindale Avenue, LONDON, NW9 5HT. Closing date for application: 31st July 1985. (6992)A

FOOD RESEARCH INSTITUTE, READING FOOD MICROBIOLOGY DEPARTMENT MICROBIOLOGIST, BIOCHEMIST

or person with similar background required to join research group devoted to developing new and improving existing methods for the detection of microorganisms in foods. This post is specifically concerned with the development of novel electrically based methods, in particular diversion of metabolic electron flow by redox mediators. An interest in bioenergetics, electrochemistry or computing would be advantageous.

The appointment will be as Scientific Officer (£6,190 to £8,561) or Higher Scientific Officer (£7,788 to £10,541). Non-contributory superannuation. Equal opportunities employer.

Qualifications: First or upper second class honours degree in Microbiology, Biochemistry or related subject with at least two years' post-qualifying relevant research experience for appointment at the higher grade.

Apply by letter and curriculum vitae to the Secretary, Food Research Institute, Shinfield, Reading, RG2 9AT.

Please quote ref 85/10. (7042)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF ANIMAL
PHYSIOLOGY AND NUTRITION

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post available from 1 October 1985 for a fixed term of two years.

Applicants must have or shortly expect to obtain a PhD in neurophysiology or a closely related subject.

The project involves a study of the effects of visceral stimuli, including gastrointestinal hormones, on single unit activity in the vagus and splanchnic nerves.

Salary on the IA Range for Research and Analogous Staff (£7,520 — £12,150) (under review), according to age, qualifications and experience.

Informal enquiries may be made to Dr J M Forbes (tel (0532) 431751 ext 7389 or 7385).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 61/20. Closing date for applications 25 July 1985. (7013)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF
RADIOTHERAPY
Cancer Research Unit
JUNIOR RESEARCH
ASSOCIATE

Applications are invited from graduates for a post of Junior Research Associate funded by the North of England Cancer Research Campaign tenable for three years from 1st August 1985. Applicants should hold or expect to receive a good honours degree in a biological science subject. The project will be concerned with the analysis of DNA repair mutants of mammalian cells and the molecular cloning of human DNA repair genes.

Commencing salary will be £6,600 per annum on the range 1B scale.

Applications, together with the names and addresses of three referees should be sent by not later than Thursday, 25th July 1985 to Dr I D Hickson, Cancer Research Unit, University of Newcastle upon Tyne, The Royal Victoria Infirmary, Newcastle upon Tyne, NE1 4LP. (7030)A

UNIVERSITY OF CALIFORNIA

DEPARTMENT OF PHYSICS
ENDOWED CHAIR
PROFESSOR OF PHYSICS

The UCLA Physics Department has an open Endowed Chair position. An appointment will be considered in any field of experimental or theoretical physics. The successful candidate will have a regular University of California tenured faculty position; the endowment income will support the candidates' program.

The successful candidate will be

KINGSTON POLYTECHNIC

Faculty of Science
School of Geological Sciences
LECTURER II/
SENIOR LECTURER IN
GEOLOGY

(Mineral Deposits Geology/Metamorphic and Structural Geology)

Applications are invited for a post of Lecturer II/Senior Lecturer in Geology which is available from 1st September 1985. Applicants should have a high research potential and a strong interest in teaching. Preference will be given to candidates with experience in either mineral deposits geology or metamorphic and structural geology. The successful candidate will be expected to make industrial contacts with a view to developing consultancy.

Salary range L II/SL: — £8,226 — £14,739 including London allowance (under review).

Details and application forms (to be returned by 29th July) from Personnel Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel 01-549 1366 ext 287/205. (7019)A

expected to lead an internationally recognized research program, and to teach at the graduate and undergraduate level.

Applicants should send a curriculum vitae, a brief statement of past, present, and future research interests, and the names of 5-10 referees to C Kennel, Chair, Department of Physics, University of California, Los Angeles, CA 90024.

The department is especially interested in identifying women and minority candidates.

The University of California is an affirmative action/equal opportunity employer. (NW1435)A

THE UNIVERSITY OF MANCHESTER POSTDOCTORAL RESEARCH ASSOCIATE

DEPARTMENT OF
CHEMICAL PATHOLOGY

Applications are invited for this post to join a group producing monoclonal antibodies to peptides of clinical importance. Candidates should possess a PhD, have wide experience in methods of peptide chemistry including (immuno) affinity chromatography and preferably monoclonal antibody production and ELISA, and be capable of initiating and expanding research in the agreed field(s) of study on minimal supervision. This is a 2 year appointment starting no later than September 1st, 1985. Salary range pa: £7,520 — £12,150. Superannuation.

Applications, including CV and names, addresses and telephone numbers of 3 referees, should be sent to Dr A. White, Department of Chemical Pathology, Hope Hospital, Salford M6 8HD, from whom further information may be obtained (tel 061-789-7373, extension 212). (6989)A

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

DEPARTMENT OF IMMUNOLOGY
RESEARCH OFFICER

required for a 3 year MRC funded post to assist in a study of the fourth component as a polymorphic marker within the MHC. The work will involve production of monoclonal antibodies and their use in immunoelectrophoresis which will be combined with serological studies of human anti-C4.

Candidates must have a first or good second class honours degree in an appropriate subject.

Salary will be £6,600 plus £1,233 London Allowance, rising to £7,520 plus £1,233 London Allowance in the third year.

Application forms and further particulars from the Personnel Office, Royal Postgraduate Medical School, 150 Ducane Rd, London W12 0HS quoting ref: 21/205/N.

Closing Date: 25 July 1985.

(6994)A

Brighton Polytechnic

DEPARTMENT OF PHARMACY

Applications are invited for the following SERC CASE Awards:

- 1 Diffusion of antibiotic molecules through biopolymer gels, in conjunction with Beecham Pharmaceuticals Research Division;
- 2 Evaluation of the ciliotoxicity of pharmaceuticals, in conjunction with the Wellcome Foundation.

Applicants should possess a good honours degree in Pharmacy, Physiology, Biochemistry or a related discipline. Normal SERC conditions apply and candidates will be expected to register for a higher degree.

Further information and forms of application may be obtained from Personnel Department, Brighton Polytechnic, Mithras House Moulsecoomb, Brighton BN2 4AT. Telephone 0273 693655 Ext. 2536. Closing date July 15, 1985. (7054)A

UNIVERSITY OF BIRMINGHAM

Faculty of Medicine and
Dentistry

DEPARTMENT OF MEDICAL
MICROBIOLOGY
RESEARCH ASSOCIATE

is required to work on molecular biological/immunological aspects of research into a herpes virus vaccine. A background in virology/microbiology/biochemistry or immunology would be beneficial but not essential.

Post available for 12 months from starting date. Salary on scale £6,600 — £8,920 with superannuation.

Applications (3 copies) to Assistant Registrar, Medical School, Birmingham B15 2TJ by 26th July 1985. Quote ref RA/MM/GRS. (7048)A

TWO POSTDOCTORAL POSITIONS

are available immediately for a Ph.D. biochemist and a molecular biologist to participate in studies of gene regulation by steroid receptors. Projects include the purification and characterization of human estrogen and progesterone receptors, cloning of the corresponding genes and preparation of monoclonal antibodies. Experience with steroid receptors, protein purification and analysis, monoclonal antibody production and/or recombinant DNA techniques is desired. Salary is negotiable.

WORKSHOPS

DNA SEQUENCING WORKSHOP

GIBCO BRL are pleased to announce a DNA sequencing workshop to be held in Glasgow from 19th–22nd August 1985. The workshop will consist of three days of lectures, discussions, demonstrations and practical experimentation in various aspects of sequencing.

Further details, regarding course content, workshop fee and accommodation will be available on request.

Application and inquiries to M McAlevy, GIBCO BRL, Trident House, Renfrew Road, Paisley, Scotland. Tel. No. 041-889-6100 (7045)V

STUDENTSHIPS

**UNIVERSITY OF
BIRMINGHAM AND THE
GENERAL HOSPITAL
SERC-CASE STUDENTSHIP**

Applications are invited for a studentship in collaboration with Beechams Research Laboratories to investigate the pathogenesis and treatment of chronic bronchial sepsis. The work will involve developing immunoassays for antibiotics, — Lactamases and host immune response to lung pathogens.

Send a CV with names and Tel Nos of two referees as soon as possible to Dr D Burnett, Clinical Teaching Block, The General Hospital, Steelhouse Lane, Birmingham B4 6NH. Tel 021-236-9922.

(7023)F

**UNIVERSITY OF
NOTTINGHAM**

**DEPARTMENT OF PHYSIOLOGY
AND ENVIRONMENTAL SCIENCE
SERC-CASE
POSTGRADUATE
STUDENTSHIP**

A studentship is offered in collaboration with Asmer Seeds Ltd. The research will involve the production of novel interspecific and intergeneric hybrids between the tomato and wild relatives. Particular attention will be given to developing tissue culture techniques for rescuing hybrid embryos between the tomato and the potato relative, *Solanum tuberosum*. The aim is to provide new sources of cold tolerance and frost resistance for the tomato breeder. The studentship is tenable for 3 years from 1st October, 1985; with a view to reading for the degree of PhD. The student will be expected to have obtained an upper second class honours degree.

Applications, including a curriculum vitae should be sent without delay to Dr I B Taylor, Dept of Physiology and Environmental Science, University of Nottingham School of Agriculture, Sutton Bonington, Nr Loughborough, Leics. (7034)F

**UNIVERSITY COLLEGE
CARDIFF**

**DEPARTMENT OF PHYSIOLOGY
PhD STUDENTSHIP**

Applications are invited for a Research Studentship in a project concerned either with: a) Synaptic interactions in the central visual system. b) Modulation of sensory transmission through thalamic relay nuclei.

The projects will take place in well equipped MRC funded laboratories and will offer access to a wide range of the latest techniques. Applicants should have a First or Upper Second Honours Degree in a relevant scientific subject. Those interested should apply to Professor A M Sillito, Department of Physiology, University College, PO Box 78, Cardiff CF1 1XL, enclosing a brief Curriculum Vitae and the names and addresses of two referees. Informal enquiries can be made to Professor Sillito by telephone on 0222 44211 Ext 2062, and potential applicants will be welcome to visit the laboratories.

(7025)F

**THE CHINESE
UNIVERSITY OF
HONG KONG
Faculty of Medicine
Department of
Biochemistry**

Applications are invited for a Royal Hong Kong Jockey Club Research Studentship, commencing September 1985, leading to the degree of Ph.D. The successful candidate will join an active research group investigating the molecular basis of amino acid transport in mammalian erythrocytes and other cell types.

Applicants should have a first or upper second class honours degree in Biochemistry or a related discipline and should have a strong interest in membrane biochemistry. Candidates with an existing postgraduate qualification (M.Sc. or M.Phil.) are encouraged to apply.

Applications, containing a CV and names and addresses of two professional referees, should be sent as soon as possible to Dr D.A. Fincham c/o Physiological Laboratory, Downing Street, Cambridge CB2 3EG, U.K., from whom further particulars may be obtained (Tel: Cambridge (0223) 64131, Ext. 223). (W2011)F

FELLOWSHIPS

**EMBO
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN
MOLECULAR BIOLOGY
Autumn 1985 — Awards**

Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R. Germany. (W1893)E

**THE ANIMAL VIRUS RESEARCH INSTITUTE
POST-DOCTORAL FELLOWSHIP IN
MOLECULAR BIOLOGY
(Funded by The Overseas Development
Administration)**

Applications are invited for a 4 year fellowship (beginning October 1st 1985) to work on analysis of the genome of capripox viruses and their development for use as a eukaryotic vector system.

The successful candidate will work with Dr Donald Black in The Division of Molecular Biology. He/she should have a degree in Biochemistry or a related subject and a PhD. Experience with expression systems and eukaryotic gene analysis would be an advantage.

The salary will be in the scale £7,788 to £10,541 (Higher Scientific Officer Grade). Sick leave and non-contributory superannuation schemes, 22 days annual leave. Accommodation may be available. The AVRÍ is an equal opportunity employer.

Application to include a curriculum vitae and the names of two referees should be sent as soon as possible to the Secretary, Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey GU24 0NF. Tel. 0483 232441. (7010)E

**ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE
(University of London)
ACADEMIC DEPARTMENT OF
PHARMACOLOGY
JUNIOR RESEARCH
FELLOWSHIP**

Applications are invited from graduates with good honours degrees in Pharmacology or related subjects for a Junior Research Fellowship commencing in October 1985. The successful candidate will be expected to register for a higher degree in the University of London and work in endocrine pharmacology. The conditions of the fellowship are similar to those of SERC/MRC studentships.

A curriculum vitae and names of two referees should be sent to Professor J R Hodges, Academic Department of Pharmacology, Royal Free Hospital School of Medicine, Rowland Hill Street, London, NW3 2PF. (7005)E

**POSTDOCTORAL
FELLOWSHIP IN MOLECULAR
BIOLOGY/ BIOCHEMISTRY**

Position available in Department of Microbiology at SUNY Stony Brook to study Adeno-associated virus genetics, vector construction, immunology or DNA replications. Send CV and references to Dr Nicholas Muzyczka, University of Florida, College of Medicine, Box J226 JHMC, Gainesville, FL 32610. (NW1901)E

ZWO space research organisation of the Netherlands
Laboratory for space research Groningen

post doctoral fellowship

in sub-mm heterodyne techniques for
astronomy.

The Laboratory has a 2-4 year position for a post doctoral astronomer/instrumentalist to participate in the development, construction and application of sub-mm heterodyne equipment for use at ground based and balloon borne telescopes. Efforts are concentrated on the development of superconducting mixers (sis and jcn) at frequencies between 300 and 1000 ghz, and on mixer arrays.

Experience in the field of sub-mm astronomy and related experimental techniques is required, preferably with mixer development.

The candidate will be employed by the Netherlands organization for the advancement of pure research (Z.W.O.). The salary will be according to the Dutch government scales for research positions.

Applications should be sent to the head of the personnel office, bureau SRON, Beneluxlaan 21, 3527 HS Utrecht, The Netherlands and must include a curriculum vitae, a List of publications, research plans for the period at the space research Laboratory and should arrive by August 1, 1985. Candidates have to provide names of two referees.

Detailed information can be obtained from Dr. Th. de Graauw, Laboratory for space research, Groningen, P.O. Box 800, 9700 AV Groningen, The Netherlands. Phone 050-116695.

(W1985)E

National Research Fellowships QUEEN ELIZABETH II AWARDS

The Australian Government has established the National Research Fellowships — Queen Elizabeth II Awards to replace the previous Queen Elizabeth II Fellowships and Queen's Fellowships Schemes. Under this Scheme, 15 awards will be made annually. Fellowships may be taken up in industry, universities, colleges of advanced education or government research organisations in Australia and are normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award. The awards are for high quality research work in one of the three categories described below:

1. **FUNDAMENTAL RESEARCH**
2. **INDUSTRY BASED RESEARCH**
3. **RESEARCH IN PRIORITY AREAS OF NATIONAL INTEREST**

Priority areas of National Interest may include:

- Research and development into products and processes, marketing, trade and social and legal issues concerning high technology areas such as:
 - energy technology
 - information technology and communications
 - materials technology
 - biomedical technology
 - biotechnology
 - raw materials processing
- Manufacturing technology
- Productivity
- Income, wealth and social inequality
- Social and economic issues affecting training and employment with particular regard to those affecting women and youth
- Occupational safety and health
- Social and economic implications of ageing
- Aboriginal Affairs

- Provision of services e.g. welfare, transport, health care
- Marine Sciences and Technologies

QUALIFICATIONS

Fellowships will be awarded to persons holding a Ph.D or equivalent qualifications, or equivalent research or professional experience in one of the disciplines available under the National Research Fellowships Scheme. The decisions regarding equivalent qualifications will be made on a case by case basis. Recommendations for the award of Fellowships will be made to the Minister for Science by an Advisory Committee. Awards will, in general, be restricted to applicants who are not more than 30 years of age when applications close.

ELIGIBILITY

Fellowships will be awarded on merit to suitably qualified persons.

SALARY

\$27,414 (Australian) per annum — increased to \$29,763 per annum at age 28 years.

TRAVEL EXPENSES

Necessary travel expenses are payable.

APPLICATIONS Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from: Executive Officer, National Research Fellowships Scheme, Department of Science, P.O. Box 65, Belconnen, A.C.T. 2616, Australia.

The next round of awards will be announced in December 1985. Applications received after the closing date of 10 September, 1985 will not be considered. People who applied for the earlier round which closed on 17 May 1985 will also be considered for this round and need not reapply. (W2003)E

UCG Coláiste na hOllscoile Gaillimh

UNIVERSITY COLLEGE GALWAY
IRELAND

POST-DOCTORAL RESEARCH FELLOWSHIPS (5)

Applications are invited for post-doctoral research fellows to work on the following topics:

- (1) "The Cloning and Analysis of the Estrogen Receptor Gene". This project is in collaboration with groups in Strasbourg and Chicago and is funded by the Cancer Research Advancement Board of Ireland. Interested applicants should contact Dr Frank Gannon, Department of Microbiology.
- (2) "The Direct Analysis of the Fertilizing Ability and Chromosomal Constitution of Bovine Spermatozoa" funded by the National Board for Science and Technology. Applicants with interests in reproductive biology, physiology, cytogenetics or a related field should contact Professor James A. Houghton, Department of Microbiology.
- (3) "Molecular Genetics Studies on Amino Acid Producing Strains of *Corynebacteria*" funded by the National Board for Science and Technology. Interested applicants should contact Professor L.K. Dunican, Department of Microbiology.
- (4) "Molecular Cloning of $\Delta 12$ desaturase" funded by the National Enterprise Agency of Ireland. Applicants should contact Dr D.R. Headon, Department of Biochemistry.
- (5) "Characterization and Molecular Cloning of Bovine INHIBIN" funded by the National Board for Science and Technology. Dr D.R. Headon, Department of Biochemistry.

Applications including Curriculum Vitae should be addressed directly to the project leader at University College, Galway, Ireland, Tel. No. (091) 24411, from whom further details of the project may be obtained.

(7035)C

UNIVERSITY OF READING

DEPARTMENT OF MICROBIOLOGY POST-DOCTORAL RESEARCH FELLOW

Applications are invited for this Fellowship which is supported by MRC and is for a fixed period of two years from 1 September 1985 with possible extension. The project under Professor J W Almond, is to study the molecular basis of poliovirus neurovirulence using infectious, cloned cDNAs. The investigation forms part of a larger programme concerned with the de-

velopment of new prophylactic and therapeutic agents against medically important picornaviruses. Previous experience of recombinant DNA techniques and/or of virology would be an advantage. Starting salary will be up to £9,390 pa.

Candidates (PhD) should apply for application forms, quoting Ref R 30A, to Personnel Officer, University of Reading, Whiteknights, PO Box 217, Reading, RG6 2AH, telephone (0734) 875123 ext 233. Dr Almond, currently at the University of Leicester, is Professor elect of the Department of Microbiology at the University of Reading. (7021)E

THE MACAULAY INSTITUTE FOR SOIL RESEARCH SWAP RESEARCH STUDENTSHIP

Applications are invited from candidates who hold, or expect to obtain in 1985, a good honours degree in physical or analytical chemistry for a research studentship at the Macaulay Institute.

Methods for the determination, in surface and soil waters, of the forms of aluminium toxic to fresh water biota will be evaluated and new methods for the speciation of aluminium, including the use of HPLC fractionation with graphite furnace atomic absorption spectrometry, developed. These methods will be applied to water samples from catchment studies of the interaction of acid rain with vegetation and soil in modifying the acidification of streams and the release of aluminium into them. This 3-year study will be part of the Surface Water Acidification Programme (SWAP) under the auspices of The Royal Society, The Norwegian Academy of Science and Letters and The Royal Swedish Academy of Sciences. The holder of the studentship will be registered for the degree of Doctor of Philosophy of the University of Aberdeen.

Further information may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, AB9 2QJ, to whom applications giving the names and addresses of three referees should be sent by 22 July 1985. Quote Ref. SWAP/5/85. (6990)F

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOLOGICAL SCIENCES POSTGRADUATE STUDENTSHIPS IN BOTANY

Applications are invited for two SERC-funded studentships tenable from October 1985:

(a) an 'ear-marked' award to Dr Jonathan Weyers to support research funded by SERC grant GR/D/03680 on solute relations of stomatal guard cells. The project will involve the preparation of epidermal strips and guard cell protoplasts, and the identification and quantification of solutes involved in stomatal movements using a range of techniques (including emission flame spectrometry, radioassay by scintillation counting, TL, HPL, and GL chromatography, enzymic analyses and electron microscopy).

(b) an award for research into oxygen build-up in cells of aquatic phototrophs to be supervised by Professor J A Raven. Quantification of this build up in plants with a 'CO 22 3 concentrating mechanism' would involve use of a variety of O 22 3 microelectrode, mass spectrometric and gas chromatographic techniques. Subsequently, the significance of the build-up for photosynthesis, and other, metabolism could be explored.

Applicants for the above studentships should have or expect a good Honours degree in botany or a related subject. Applicants, stating experience, should be sent to either Dr J D B Weyers or Professor J A Raven, Department of Biological Sciences, University of Dundee, DUNDEE DD1 4HN, Tayside, UK. (6991)F

VACANCIES

PhD STUDENTSHIPS

Northern Carbon Research Laboratories,
School of Chemistry,
Bedson Building,
University of Newcastle upon Tyne,
Newcastle upon Tyne NE1 7RU

Two CASE studentships are available in the above Laboratories, leading a PhD by research.

1 DEVELOPMENT OF CARBON-CARBON COMPOSITES

Supported by SERC and T & N Materials Research Ltd, Lancashire.

The aim of the research is to develop a new generation of carbon-carbon composites based on an understanding of liquid crystals formed from pitch.

2 COMBUSTION OF LIGNITES IN POWER GENERATION

Supported by SERC and Babcock Power Ltd, London. The aim of the research is to characterise lignite coals by FTIR, adsorption methods, reflectance microscopy and combustion behaviour in a transient flow reactor.

The studentships are suitable for graduates (BSc Hons) in Chemistry, Geology, Materials Science.

Applications and requests for the further details should be sent to Dr H Marsh or Dr I A S Edwards at the above address (telephone 0632 328511 Ext 3085/3084). No special forms are needed. Enclose a CV. (7006)F

UNIVERSITY OF READING

AGRICULTURAL BOTANY DEPARTMENT POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited for two studentships to commence in October 1985

(a) A MAFF STUDENTSHIP

to work on the agro-ecology of *Phalaris paradoxa*, an annual grass weed which has recently become a problem in arable production in some parts of Eastern England. Studies of germination requirements, control and genetic variation will be undertaken. The work will be supervised by Dr D S H Drennan.

(b) An ODA STUDENTSHIP

to work on physiological and biochemical aspects of ripening in commercially important tropical fruit. The work will be jointly supervised by Dr A K Thompson (Tropical Development and Research Institute, London) and Dr P John.

Applicants should have at least an upper second class degree in an appropriate subject. Telephone enquiries can be made to Dr Drennan (0734 875123 ext 7923) or Dr John (Ext 7900). Applications, including a curriculum vitae and names of 2 academic referees, should reach Dr Drennan or Dr John before 19 July 1985. (7018)F

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY AN SERC STUDENTSHIP

is available in the laboratory of Dr W John Ingledew, Department of Biochemistry and Microbiology.

The project is on the 'Relationship between the function and organisation of the respiratory chains of *Escherichia coli*', and is linked with other continuing projects in the laboratory. The techniques involved in the project will concentrate on the use of stopped and quenched flow kinetics methods, combined with detection by optical spectroscopy and electron paramagnetic spectroscopy. Work on the determination of anisotropic arrangement of the components in the cell membrane will also be pursued. For reference see Ingledew and Poole (1984) Microbiol Rev (48) 222 — 271.

Applicants should hold or expect to hold at least an upper second class honours degree in one of the following subjects or a related subject — Biochemistry, Biophysics, Microbiology, Chemistry.

Application and requests for further details to Dr W J Ingledew, Department of Biochemistry and Microbiology, University of St Andrews, St Andrews, Fife KY16 9AL. (7036)F

ASSISTANTSHIPS

UNIVERSITY OF GLASGOW
DEPARTMENT OF BIOCHEMISTRY
Applications are invited for a SERC funded

POSTGRADUATE RESEARCH ASSISTANTSHIP

to investigate aspects of the Biosynthesis, import and assembly of pyruvate dehydrogenase multi-enzyme complex in mammalian cells. The work will be part of a research programme supervised by Dr J Lindsay.

Suitable applicants will have an opportunity to study for a PhD; some experience in tissue culture, protein purification and immunological techniques would be an asset. The salary will be on the 1B scale plus USS. The appointment, which will begin on 1st October, 1985, or soon as possible thereafter, is for a maximum of 3 years.

Applications (one copy), giving the names of two referees, should be sent to Dr J G Lindsay, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ, from whom further details may be obtained. (7057)J

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for postdoctoral

SENIOR RESEARCH ASSISTANTSHIP

tenable for two years, from October 1985, to work with Dr J Munro and Dr D Parker on the synthesis and characterisation of electroactive, polymeric thin film. Applicants should have a strong background in electrochemistry; some knowledge of surface chemistry is also desirable. The starting salary is £7,520 — £8,920 on RA 1A plus superannuation (under view).

Applications (3 copies) naming three referees should be sent by July 1985 to The Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (7032)

UNIVERSITY OF NOTTINGHAM
Nottingham NG7 2RD
POSTDOCTORAL RESEARCH ASSISTANTSHIP (Grade 1A)

DEPARTMENT OF ZOOLOGY
Applications are invited for a post-doctoral research assistantship (Grade 1A) to work with Dr D I de Merai on a crystallin gene expression in transdifferentiating chick embryo cell cultures. The techniques to be used will include cloning, Northern blotting, primer extension analysis and nuclear runoff transcription assays. Molecular biologists with experience in some or all of these techniques would be suitable for this post, which is funded by ARC. The appointment will be made at the bottom of the 1A scale, and the duration will be three years, starting 1st January 1986.

Applications, giving a full CV and names and addresses of two referees, should be sent to Dr de Merai at the above address by 15th September 1985. (7031)P

UNIVERSITY OF OXFORD
Dyson Perrins Laboratory
STREPTOMYCES BIOSYNTHETIC ENZYMES: Cloning and Application to Novel Antibiotic Synthesis

Applications are invited for a post-doctoral research assistantship to work on the cloning, isolation and characterisation of antibiotic biosynthetic enzymes from Streptomyces and their application to the enzymatic synthesis (in vitro and in vivo) of novel antibiotics. This work will be performed in collaboration with Dr K F Chater, complementing current research on streptomyces genetics at the John Innes Institute in Norwich. Candidates with experience of molecular biology, enzymology or bioorganic chemistry are preferred. The appointments are on the RA1A scale with starting salary up to £8,920 pa plus USS according to age and experience and would be initially for one year from October 1985 with the possibility of extension.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr A J Pratt, Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY. (7043)P

APPOINTMENTS WANTED
advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of \$8 per line. Personal Box Numbers \$10.00). Advertisements must be pre-paid and sent to: *Nature Classified (Appts Vtd)*, 65 Bleecker Street, New York, NY 10012. (890)B

THE OPEN UNIVERSITY
Faculty of Science
RESEARCH ASSISTANTSHIP ON PLATINUM GROUP ELEMENTS

Applications are invited for an EEC-funded research assistantship to study the process controlling the distribution of the Platinum Group Elements in ophiolite complexes. Candidates will be expected to hold a good first honours degree in geology and have specialised to some extent in geochemistry. The assistantship is available immediately for 1 year and may be extended for a further 2 years. Registration for an O U higher degree may also be possible.

Salary will be on the 1B Scale for Research and Analogous Staff (£6,600 — £8,920 pa under review). Starting salary will depend on age and experience but will not exceed £7,980 pa.

Application forms and further particulars are available from Dr J W R Smith (4850/1), Administrative Assistant Science (4850/2), Faculty of Science, The Open University, Walton Hall, Milton Keynes, MK7 6AA or telephone Milton Keynes (0908) 653993: there is a 24 hour answering service on Milton Keynes 653868.

Closing date for applications: 19th July. (7014)P

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
POST-GRADUATE RESEARCH ASSISTANTSHIP

Applications are invited from graduates with a good honours degree or undergraduates who expect to obtain at least an upper second class honours degree this year for a British Diabetic Association supported post.

The successful applicant will work with Dr A Burchell on a project investigating the genetic regulation of hepatic microsomal glucose-6-phosphatase during diabetes. The project will involve extensive use of protein chemistry and recombinant DNA technology, and applicants should have a strong interest in one of these disciplines.

The post is for three years duration starting late Summer 1985 and the salary will be on the Research & Analogous Range 1B scale (£6,600 — £7,520 per annum).

Informal enquiries may be made to Dr A Burchell (Tel 0382 23181 ext 4237).

Applications containing a full Curriculum Vitae and the names and addresses of three referees should be sent to the Personnel Officer, The University, Dundee, DD1 4HN, as soon as possible. Please quote Ref EST/76/85J. (6998)P

CONFERENCES & COURSES

ADVANCED COURSE IN FLOW CYTOMETRY; ANALYSIS AND FLOURESCENCE ACTIVATED CELL SORTING
Paris, September 9-14, 1985

Sponsored by: The Cancer Research Association (ARC) — Jacques Crozemarie, President, and the "Centre Technique pour le soutien de la Recherche sur le Cancer des Laboratoires et Formations du Centre National pour la Recherche Scientifique" (C.N.R.S.)

A Course in Flow Cytometry will be offered with special emphasis on cell biology. Themes will include Multiparameter cell sorting, cell lineage studies, tumor cells characterization, gene amplification selection, cloning of genes by transfection, somatic cell genetics, hybridoma variant selection, liposome endocytosis, cell cycle analysis. Brd U and cytokinetic studies, mathematical modeling of the cell cycle, computer system for multiparameter data analysis, cytochemistry and new fluorochromes, karyotype analysis, pumped dye lasers, emission anisotropy.

The Course will consist of lectures, laboratory demonstrations and problem solving sessions.

Course Directors: Harry Crissman (Los Alamos National Laboratories), Claude Rosenfeld (INSERM, Villejuif, France)

Organizers: L.A. Herzenberg (Stanford University, USA), P. Le Bouteiller (Centre d'immunologie de Marseille-Luminy, France), Z. Mishal (C.N.R.S., Villejuif, France), M. Monsigny (Centre de biophysique moléculaire, Orleans, France), J.L. Roti-Roti (Washington University of St. Louis, USA).

Lecturers will include the above plus: B. Bagwell, S. Cram, Z. Darzinkiewicz, P. Dean, M. Goldberg, J. Gray, P. Horan, C. Julien, M. Loken, P. Manoni, H.S. Micklem, K. Muirhead, D.R. Parks, A. Truneh.

Course tuition: \$500 (5 000 FF) includes laboratory fees, manual, coffee breaks, lunches and an optional Flow Cytometry Certificate.

Send C.V. and tuition deposit \$50 (500 FF) to the local Course Director (max. 50 persons).

Dr. Claude Rosenfeld,
INSERM Unite 253,
Groupe Hospitalier Paul Brousse,
16 bis avenue Paul Vaillant Couturier,
94804 Villejuif, France.

Application deadline June 30 1985, priority given to early applicants. (W1919)C

MAGISCAN

THE TOTAL IMAGE ANALYSIS SYSTEM

Chromosome analysis, Dosimetry, 3-D reconstruction, 2-D gel electrophoresis, just a selection from the growing range of dedicated applications systems now available for the Magiscan. These applications packages and the comprehensive, easy-to-use general purpose software make Magiscan indispensable in any clinical or research laboratory.

Magiscan now has an expanded range of input and output options and increased speed and storage provided by its inbuilt Winchester disc.

Magiscan provides the facts – leaving you to make those other important daily decisions.

Whether you are involved in research or evaluation, contact Joyce-Loebl's team of application specialists to find out how Magiscan can help.

BIOSYSTEMS UPDATE

Introducing the high performance, low cost, fully automated DNA Synthesizer.

The new Model 381A DNA Synthesizer optimizes the efficient phosphoramidite chemistry to reliably and economically produce high quality oligonucleotides.

Automatic rinsing and priming of reagent lines when new chemicals are added, menu-driven software and stable, prepackaged reagents make the 381A easy to use.

Results and Affordability

The new Model 381A produces high purity, defined-sequence oligonucleotides quickly and economically. It delivers routine coupling yields of 98–100% and the capability to synthesize oligonucleotides with more than 100 bases.

The 381A is a *complete* instrument-reagent system with the proven chemistry and precision design that have made Applied Biosystems the world leader in synthesis technology. Affordably priced, the 381A brings every researcher the speed and reproducibility of automated DNA synthesis with the convenience of an in-lab instrument.

Advanced Capabilities

The 381A can produce 50 to 100-mers providing greater flexibility in gene synthesis strategy by minimizing the number of purifications and ligations. With the efficient phosphoramidite chemistry, probes and primers can often be used without purification. Specific primers for Sanger dideoxy sequencing can be ready for use in less than 18 hours.

Production of mixed probes can be ac-

complished without any premixing of bases, and the addition of unusual bases can be completely automated. Small amounts of probes and primers or up to 10 mg of DNA for physical studies can be made economically and automatically with no hardware modifications.

Fully Programmable

The 381A can be operated with the standard synthesis cycle or used to develop and store new chemistry methodologies incorporating existing or user-defined functions. Users can optimize cycles for up to five different nucleotides or derivatives. Integral battery with automatic re-start preserves synthesis parameters and user-designed cycles when power is interrupted.

Immediate Delivery

Compare and you'll agree: The 381A is a remarkable performance/price value. Your local Applied Biosystems representative has all the information for immediate purchase and shipment. Contact us at one of the offices listed below or key reader service number 08.

A better way to get uniform band s

Wedge-sha

A

C

B

D

No longer need you resort to multiple loading with its increased time and greater required sample volumes. Whether for nucleotide separations in agarose gels or sequencing in acrylamide gels, the technique of wedge-shaped field strength gradients lets you get linearly spaced bands for maximum resolution and ease of reading. Two new instrument systems from LKB render the technique rapid, reliable and above all, reproducible.

In the Maxiphor™ horizontal electrophoresis unit (A), it is the simplest thing in the world to pour wedge-shaped agarose bridge gels directly on the central platform when adjustable legs beneath the cathode dam are extended. Gels can be run rapidly at high power even without external buffer circulation, the half-litre reservoir providing enough internal cooling capacity even at 500 volts. Want to use the Maxiphor for constant thickness bridge or submarine gels? Just as easily done. And you can run up to 40 samples every time.

For greatest economy and speed in fragment separations, the sibling Miniphor™ unit (B) with its integral cooling jacket lets you run submarine gels at very high power. Companion to both units is the LKB constant power supply (C) that permits regulation to 1 volt or 1 milliamp with 1 minute precision for automated runs. And completing the system is the MacroVue™ transilluminator (D) whose optical design permits you to detect as little as 1 ng DNA in a single band. This instrument makes publication grade photography easy.

g in DNA/RNA electrophoresis

gradient gels

In the Macromould™ unit (E), you can cast wedge-shaped acrylamide gels that are covalently bonded to a glass plate for maximum support. (If you are interested in constant thickness gels, you can cast them as thin as 0.1 mm, allowing much greater use of ³⁵S labeling with its attendant virtues of lower scattering and better resolution – without wrapping or refrigeration – as well as longer half-life and improved safety.)

When gels are run in the Macrophor™ vertical electrophoresis unit (F), the unique thermostatic plate ensures constant high temperature, letting you use every millimeter of width to run a full 36 samples – without smiling. Consorts to the Macromould and Macrophor are the compact MultiTemp™ II thermostatic circulator (G) and the Macrodrive™ 5 high capacity power supply (H) with its digital display. And just as with the horizontal electrophoresis units, you can get here a full complement of chemicals, accessories and technical literature.

Two informative illustrated bulletins are waiting for you. Request them today.

25-Hydroxy vitamin D

Amersham's new [^3H] assay system is the reliable and convenient way to measure 25-hydroxy vitamin D in serum. Fully effective sample purification and robust methodology give you rapid results and ensure your samples are . . .

**measured
with
confidence**

Also available is an assay system for 1 α ,25-dihydroxy vitamin D and a full range of labelled compounds for use in the vitamin D research area.

NATURE VOL. 316 11 JULY 1985

COVER

The mitotic spindle is responsible for the equipartition of chromosomes during cell division. The cover shows a chain of dividing diatom cells stained with DAPI to visualize the separating masses of chromosomes. The letter beginning on page 170 shows that isolated diatom spindles are able to undergo spindle elongation *in vitro*.

THE LANGMUIR-BLODGETT INSTRUMENT

If advanced molecular electronics is your field of interest, this is the Langmuir-Blodgett instrument for you. KSV offers state of the art thin film technology of tomorrow... today. The new KSV 2200 LB monolayer laboratory achieves the performance and reliability demanded by the fabrication of the most sophisticated LB-films.

The Automatic Film Collector system was developed to allow unsupervised deposition of ordered layers of LB-films, while consistent quality is guaranteed by the microprocessor-controlled Dynamic Film Control system.

The requisite ultra-clean atmosphere is created by the rugged laminar flow enclosure.

To make things even better, you have direct access to the KSV 2200 LB system from your personal computer through a standard RS-232C serial interface. Convenient and rapid data acquisition and processing with KSV software means flexibility and fast analysis of results – with the swiftness and accuracy you have only dreamed about. You can concentrate on the information, not the instrumentation.

Discover the state of the art thin film technology with KSV 2200 LB – the leader in Langmuir-Blodgett films.

Index

Comprehensive annual indexes of subject and author are available for all issues of **Nature** from 1971 to 1984.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable)

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington). Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from *Nature* should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.

With Sequencing Grade Triphosphates From Pharmacia

Ultrapure Deoxynucleoside Triphosphate Solutions

While often overlooked, high quality triphosphates can increase gel clarity considerably, allowing reading of up to 30% further from a single primer site. Pharmacia's solution triphosphates are the most stable, homogeneous and diphosphate free nucleotides available. In addition, they can be used without weighing, neutralization or concentration determination.

2',3'-Dideoxynucleoside 5'-Triphosphates

Ever since we provided the first commercial dideoxynucleosides in 1977, researchers have relied on our ultra-pure 2',3'-dideoxynucleoside 5'-triphosphates for the specific chain termination and low background needed in their sequencing.

Keep your results clear of the background.

Electronics in trouble worldwide

Two years of upheaval in the market for microprocessor computers have now been followed, in Britain, by stockholders' uneasiness about electronics giants. Stoicism is called for.

WHAT has gone wrong with the electronics industry? For the past decade, as the benefits of integrated semiconductor devices have become apparent not merely in the design of novel equipment such as personal computers but also in telecommunications equipment serving a traditional purpose in a novel way, prophets have been singing the praises of what the future will be like, and those with money to invest have believed what they have heard. The recent past has been traumatic for them. In the United States, the troubles began more than two years ago, when mushroom companies, large as well as small, found that their financial accounts were having to be written mostly in red. Many have since gone out of business, others have been bought up cheaply by their competitors. It is not surprising that the New York stock markets now take a more cautious view of the attractions of investing in electronics companies. Nor is it surprising that the rot has now spread outside the United States, to Britain in particular. Some manufacturers of personal computers (such as the Wales-based Dragon) went to the wall almost as soon as they began. More recently apparently solid companies have run into trouble. Acorn, the benefits of an arrangement with the BBC notwithstanding, has had to be rescued by Olivetti but may yet fail, Sinclair has been bought up by an offshoot of Mr Robert Maxwell's Pergamon Press. Now, to the general consternation, some of the giants of British electronics manufacturing are deeply offending their owners. Stockholders are asking whether the future has been indefinitely postponed.

Rail fever

Small comfort though it may be, the present trouble in electronics is not without precedent. British economic history includes one of the most vivid illustrations of how the rapid development of a new technology may be a mixed blessing for those tempted to stake their fortunes on it—the development of the railway system. During the period from 1840 to 1870, George Stephenson's example served as a powerful stimulus of investment in new railway companies. In the event, many were geographically too confined to be viable except as adjuncts of larger companies, others were discovered to have grossly overestimated the markets for which they were established and went out of business, still others (as the railway map of Britain in the 1950s shows clearly) duplicated what other companies were about. By the end of the nineteenth century, the Victorian railway boom had enabled some of those who backed it to make great fortunes, but had robbed many others of their shirts. The recent upheaval among manufacturers of personal computers has clearly run along very similar lines, but the time-scale of events has been dramatically foreshortened.

In retrospect, the course of events should nevertheless be no surprise. Companies such as Atari grew quickly on the back of a fashion of the late 1970s, young people's interest in playing

games of a novel kind on television screens. But soon after Atari had been bought by Warner Communications, the gingerbread began to go stale as the fashion changed. Warner itself seemed for a time financially vulnerable. Among manufacturers of more seriously intended personal computers, there have been two recurrent technical problems, a persistent tendency to underestimate the length of time needed to turn a good idea into a workable (and saleable) device (software as well as hardware) and the maddening issue of the degree to which one machine is compatible with another.

Service

The persistent misjudgement of market needs, especially by the smaller manufacturers, is however much more relevant. In a field so novel, for example, the need for after-sales service to help customers use what they had bought should have been plain. Yet many companies, some of them casualties of the upheaval of the past two years, appear to have left that need out of account. But is not providing such a service, especially internationally, bound to be both intricate and expensive? That is what the smaller manufacturers have been saying. Of course. But what purpose is served in the long run by marketing even technically excellent products without providing what must be regarded as services essential to their proper use? In the unsophisticated markets of a few years ago, many smaller companies calculated that buoyant sales of low-priced hardware would give them a niche from which they might afterwards expand. One of the outstanding characteristics of this part of the computer market is that the cost of hardware may be only a fraction of the total, at least when some account is taken of the time unsophisticated users must spend on learning to use what they have bought. This truth, an awareness of which is now spreading, no doubt accounts for the recent slump in sales of even technically excellent machines. Investors will no doubt take note.

The more surprising recent faltering of confidence in major British companies must be differently explained. Part of the trouble is worldwide. In New York, even IBM's share price has not continued its buoyant upward surge as people have begun to realize what should have been evident, that the years immediately ahead are bound to see both high investment in research and development and fierce competition in the marketplace. The acquisition of the communications company MCI by IBM two weeks ago will, for example, bring about novel competition with established providers of telecommunications services, in which the profits of all concerned may suffer, to the general benefit of the users of these services. That, at least, is what should happen in the United States and possibly elsewhere if the regulators and legislators who have recently been deregulating the communications market do not lose heart.

The British scene is, as always, muddier, and should be an object-lesson both for governments and investors. One powerful influence has been the conversion of British Telecom from a public communications monopoly to a private near-monopoly. The immediate result has been to destroy the market for all except the most up-to-date capital equipment in the British network. Suppliers of analogue exchange equipment, on the development of which British Telecom's predecessors and the major British suppliers were engaged as recently as 15 years ago,

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, it will be helpful if they will in future send four copies of all manuscripts offered for publication, either (as at present) to London or Washington

are now having to close manufacturing plant (which they might have expected), while the purchaser under whose umbrella they used to shelter now plans to play the international market for digital exchange equipment. The moral is that private companies that become over-dependent on a single customer (in Britain, Plessey and STC seem to be worst hit) are vulnerable in two respects: technically their pattern of activity is constrained, financially they depend on the whim of others.

There are also more immediate problems. The general depression and competitiveness of the computer market has made STC's purchase of the British company ICL seem less of a bargain than it did last year. Fierce international competition for general-purpose semiconductor chips, which has meant that prices have fallen by a factor of five within a year, has similarly afflicted the British company Thorn-EMI, the purchaser last year from the British government of Inmos, the semiconductor company. Those with an interest in these questions are now wondering which chairmen will be forced to leave which companies. Those with longer memories may recall the curious and still unexplained outburst last month by Lord Lucas, a government spokesman in the House of Lords, who surprised his audience with a recipe for the amalgamation of British electronics companies. The most obvious candidates for shotgun marriages are the companies whose balance-sheets (and share prices) have been hit by increased competitiveness of the general electronics market, but even companies such as GEC (no relation of US General Electric), which have stuck to customized semiconductor electronics for the most part, have disappointed their shareholders while maintaining their profits.

The outcome of this period of upheaval cannot, of necessity, be predicted. Indeed, even companies that have been hard hit in the past few weeks are strong industrial organizations, well able to ride out the storm. But the best-provided must be those whose interests span more than electronics pure and simple. They are best placed to swallow one or more of the others. The snag, for disappointed investors, is that in the present climate they may not wish to do so.

If the immediate future cannot be foretold, the more distant future is fortunately more predictable. Electronic computers with hugely different capacities are now well-established and productively used, while there is likely to be a lull of several years before machines of radically different architecture are working tools. So too are the technologies of telecommunications. But the marriage of the two fields has so far been half-hearted. That is why, with the increased competition between the giants of the two industries, the next decade should throw up novel opportunities for the smaller fry to become suppliers of specialized equipment; there should be plenty of niches for other companies to fill. Investors should know, however, that capital investment in research and development will be more than ever needed if they are to be filled. Meanwhile, ambitions to overtake the giants by sheer cleverness (which is not in short supply) should be surpassed. □

OPEC in the doldrums

OPEC is going through a bad patch, but remains a potentially powerful cartel.

OPEC, the Organization of Petroleum Exporting Countries, seems these days to stagger from one crisis to another. Last weekend's meeting in Vienna was no exception. After three days of talk, OPEC failed to persuade itself that there should be a system of production quotas that would restrict the amounts of oil that could be sold on world markets. Even the proposal that the total volume of OPEC production should be reduced by 7 per cent, unenforceable without production quotas, is only a formality, setting a ceiling (of 14.9 million barrels a day) believed to be higher than OPEC members now sell collectively. It is always possible that the economic climate may change before the next formal meeting of the organization, scheduled to begin on 22 July, but the prospects (for OPEC members at least) are

not bright.

Why is OPEC now apparently so weak when it seemed, in 1973 and 1979, that it could fix whatever price it chose for a barrel of crude oil and still keep its members' oil revenues at levels that satisfied their needs for overseas currency? The time-lag between 1979 and now is significant and the explanation is almost banal. The sudden jumps of price in the 1970s were shocks to the economies of the oil consumers. The short-term effects included all kinds of economic problems, stagflation in particular. One of the long-term consequences has been simple old-fashioned price resistance. Customers reconciled to prices of between \$10 and \$12 a barrel (the official price of Saudi Arabian crude oil between the first and second shocks) have changed their ways, and have taken steps to use less oil. In retrospect, it is unlikely that OPEC would have dared put the price above \$30 a barrel in 1979 if it were not that Iranian production had been halted. Since then, however, the trend of prices for the oil products sold on the Rotterdam market has been steadily downwards, in dollars and without allowing for inflation.

The driving force behind these dramatic changes is the way in which the oil consumers have managed to economize in its use. It is almost as if OPEC's 1979 round of price increases had been designed to bear out the contention of the late Shah of Iran that higher prices were the best way of ensuring that oil would be left in the ground for "future generations" to use as a source of chemicals.

The industrial trends are neatly illustrated in British Petroleum's latest *Statistical Review of World Energy*, published last month. Between 1970 and 1984, the consumption of primary energy in the United States for each unit of gross domestic product (GDP) fell by some 17 per cent. In the other industrialized countries which are members of the Organization for Economic Cooperation and Development, where energy consumption per unit of GDP has always been roughly half that in the United States, the fall since 1970 has been more dramatic — more like 20 per cent than 17 per cent.

Two quite separate trends are apparent in the figures. First, all of the industrialized countries are using less energy for each dollar's worth of wealth that they generate internally. Second, within the total pattern of energy consumption, the importance of oil is steadily declining. All this is what would have been predicted from the elementary rules of supply and demand. The only surprise is that there has been such a noticeable change in a mere six years.

So does this mean that OPEC is now finished as a determinant of the price of oil and, by extension, of other forms of energy? That is not a reasonable calculation. Part of the reason why oil consumption has been depressed since the beginning of the decade is that economic activity has been at a low ebb, and part of the reason for that long depression was the sharp increase of the price of oil. OPEC's strength has during that period been contained by a kind of negative feedback which few industrialized economies have enjoyed. Ominously, with the improvement of economic activity between 1983 and 1984, there seems to have been a sharp increase of total energy consumption which restored energy consumption to the peak that it reached in 1979. (GDP had increased in the interval.) There is always a possibility that the full restoration of prosperity will have oil companies bumping up against the now much reduced level of production by the OPEC states, for oil is for technical reasons the most ready way of meeting marginal demands.

The moral in this for the oil consumers is that they must hasten plans for the use of other energy sources. Coal consumption has grown steadily, but only slowly, in the past decade, and there is plainly a limit to the speed with which supplies can be increased. Nuclear energy similarly lives on a long time-scale (that could and should be shortened). Energy conservation measures are similarly slow to take effect. But these and other devices are, if anything, more necessary now than at any time in the past decade. The unpalatable alternative is to see the price of oil increase yet again. □

Japanese science

Selected council to replace over-democratic body

Tokyo

THE newly selected Science Council of Japan is to go into action later this month. And selected, rather than elected, is the word, for the government has had its way and turned the often-troublesome freely-elected "parliament of scientists" into a select advisory body. In the process, nearly 80 per cent of its members have been replaced.

Since 1949, the Science Council of Japan has been advising the government on science policy and promoting and coordinating scientific research both nationally and internationally. Its activities have been directed by its 210-member general council and performed through standing committees and research liaison committees involving some 1,500 scientists.

Council members used to be elected in a postal ballot, held every three years, in which virtually all of Japan's 240,000 scientists were qualified to vote. The council was thus perhaps unique among nations in providing all scientists with the right to participate directly in choosing representatives to the highest level of government: the chairman of the council had an automatic right to membership of the Prime Minister's Council for Science and Technology. Numerous successes were scored by the council over the years and many of Japan's finest research facilities grew out of its recommendations including the Nobeyama radio telescope, the Photon Factory, the Institute of Molecular Science and the Polar Research Institute.

But the council ultimately fell prey to a peril for all "grass roots" democracies, the apathy of the "moderate majority". The council has always contained a "peace" lobby which irritated the government by its opposition to nuclear power, by action that successfully prohibited research on nuclear weapons, and by demanding parliamentary action to guarantee "freedom of research" rights of scientists. It was such people that campaigned most vigorously at election time, not a cheap process for although only the sending of promotional postcards was permitted, many candidates spent as much as a million yen (US\$4,000). Over the years they gained a larger voice in the council.

In return, the government tended to pay less attention to council advice and relied more on its own advisory bodies such as the Ministry of Education's own science council. And that meant that many voters, perceiving the council's power to have lessened, became indifferent to its activities and abandoned it to "left-wingers" whose interest was more

political than scientific, or that at least is the story the government would have people believe. The affairs of the council were costing a lot of money, which had to be found by the government. Supervising elections alone, with an electorate of nearly a quarter of a million, cost 100 million yen (US \$400,000 dollars).

After a few years of dispute with the government (see *Nature* 305, 361; 1983), the council is now completely reformed (or rendered subservient, depending upon the point of view). Representatives are not directly elected but are chosen at meetings of an electoral college (the Council Selection Management Committee) which is elected, together with candidates for council membership, by the major academic societies.

French science

Horizon freed from bonds

Paris

FRENCH science seems set for another good year and perhaps for three. When the budget of the French ministry of research came up for parliamentary approval at the end of June, the Prime Minister himself, M. Laurent Fabius, opened the debate.

He told the assembly that "when the question is research, the future of our country is at stake", and said that "the whole effort of this government is found on the triangle of research, training and investment". The fact that the opposition walked out is taken at the ministry as a positive sign for 1986, when the opposition seems likely, by all opinion polls, to be returned to power. Abstentions, or a vote against the budget targets, would have been much worse than a walk-out.

The divided opposition in France, led by M. Giscard d'Estaing, M. Jacques Chirac and M. Raymond Barre, can hardly bring itself to vote for anything that the present government has done, when the popularity of the President, M. François Mitterrand, is at a low ebb. But science and technology are widely thought to be among the government's successes. Thus the innovation director of a Paris company, who "cannot stand" the present government, admitted last week that the attitudes of French academics have now "completely changed". Previously, he said, academics liked to prove that they had no time for practical affairs. Now, they compete for industrial clients.

As for money, M. Fabius told the national assembly, "two periods have marked the development of science in

The new system, along with a rule preventing anyone serving more than three terms of three years each, has led to a dramatic shift in council membership (plus a huge reduction in expenses). Of the 210 members, 163 are new. In come many of the most famous names in Japanese science, as well as a large number of very active researchers who had earlier refused to be involved. The average age of council members rises a couple of years to nearly 63, perhaps because of the influx of emeritus professors, and so does the number from the Tokyo region, up to 64 per cent of the total. Tokyo University professors alone take 17 per cent of the places, with Kyoto next at 8 per cent. Women too have done a little better, if a change from just one representative to a mere three can be called an improvement.

There is no doubt that the new council contains an extremely distinguished group of scientists who will put science before politics. The test will be whether they pay attention to the wider implications of the expansion of science they will no doubt try to promote.

Alun Anderson

France. One was under President Mendès-France and one under General de Gaulle." There was a great decline after de Gaulle (beginning with President Pompidou) in which French research and development spending fell from 3 per cent of the gross national product to 1.7 per cent. Now it has been pulled back to 2.25 per cent, which marks a very strong growth since 1980. However, Fabius was careful in his choice of date: M. Mitterrand and his government came to power in 1981, but the science budget was already beginning to increase substantially in 1980 under President Giscard d'Estaing's science minister M. Pierre Aigrain. So science spending is not a party issue.

In the meantime, M. Fabius promised to give science "an absolute priority", backed M. Curien's proposal to raise the research budget by 4 per cent a year in real terms to 1988, and set his country's sights on reaching 3 per cent of gross national product by 1990-91. "No science policy is possible without continuity", Fabius said. M. Curien's "three year plan" will create 1,400 new scientific posts per year, will increase the number of student grants and "develop mobility".

Other themes raised by M. Fabius were the linkage of the research community to industry; a "primordial" commitment to scientific development of Europe as a whole and promotion on merit. In forging links with industry and in returning to an academic meritocracy, the present government may ironically have had its greatest success — and lost most of its ideological socialist support.

West German universities

Erosion of plans for change

Hamburg

NEARLY 40,000 students took part in a demonstration against the proposed amendments to German university regulations in Bonn during June, marking another crisis in discussions that have already dragged on for two years. The present government had commissioned a group of experts to review the existing regulations, the *Hochschulrahmengesetz* (HR6) and suggest improvements. These regulations were themselves a delayed response to the student unrest in the late 1960s, and had required four years of complex negotiation before coming into force in 1976 under the then Social Democrat/Liberal government.

One important feature of the earlier proposals was to shift the balance within university committees to a wider group, making it possible for professors to be outvoted by the combined representation of students, assistants and non-academic personnel when they are not unanimous among themselves. The plan to return to the former system, supported by the Education Minister Dorothee Wilms (Christian Democratic Party, CDU), is the main reason for the students' protest, although they also object to the proposed introduction of a two-tier system of studies and the relaxation of rules for industrial research within universities.

The amendments would allow particularly talented students to take additional courses while the majority would have to complete their studies after six semesters. Critics feel that this would divide graduates into two groups, one of which would pick up the good jobs while the other would have to compete for an ever-diminishing number of academic openings. And the planned relaxation of the regulations covering research paid for by other than official sources, usually by industry, has created intense mistrust.

Minister Wilms is becoming increasingly isolated, as the students are no longer alone in their protests. Even the West German Conference of University Rectors (WRK), once the prime mover of reform, has distanced itself from the present proposals, which it believes go too far. It is even being asked whether amendments are necessary after all. Meanwhile, the education minister is losing further ground: her hopes that the new regulations would be passed before the summer parliamentary recess have been crushed.

Even states governed by CDU have started to question the need for a change. The chief minister of Rheinland-Pfalz, Bernhard Vogel, has declared that the present regulations "are better than their reputation", on the grounds that they have enabled the universities to recover from the crisis of the 1970s. This reflects what most state governments are think-

ing.

The *Länder*, which would have to implement such new regulations as are eventually embodied in a new federal law, also feel that the change is unnecessary. Most have learned to live with the present law, with all its problems. This is exemplified by Bavaria, which has adopted a law to facilitate additional financing for research which is acceptable both to industry and the universities without having had to wait for changes in the federal law.

As time goes by, the opposition grows stronger. It is now uncertain whether the new proposals, even as amended, will be accepted by the *Bundestag* and the *Bundesrat* in the next parliamentary session. Speakers for the Social Democratic Party (SPD) have moreover declared that the plan of Dorothee Wilms to undermine the principle of the comprehensive universities (*Gesamthochschule*) is unacceptable, as is the proposed dissolution of the Study Reform Commission, a body concerned with the improvement of study courses. SPD even promises that the cancellation

of the new regulations would have high priority if it were to return to power. After its recent electoral successes (see *Nature* 6 June, p.450), SPD has become very self-confident.

Second only to the students, the loudest protests have come from the universities themselves. Having come to terms with the present law, they feel that politicians should concentrate more on the real problems: the steady erosion of financial support, the fact that 1.3 million students are enrolled on courses originally planned for 800,000, the rapidly increasing trend to unemployment among graduates and the exceptionally discouraging prospects for promotion within the university system, where the available professorships were distributed too readily during the years of expansion.

Despite all the criticism, Minister Wilms is insisting on her plans. They may represent the only significant project available to her, especially if the lifetime of the present government is limited. But her proposals are becoming less and less acceptable as the debate continues. Yet if the new proposals are not soon made law, little will remain of their original obviously reactionary character. **Jürgen Neffe**

AIDS

Blood test trials inconclusive

Washington

THE first actual performance data on the acquired immune deficiency syndrome (AIDS) blood test are now in and they are a mixed bag. The test became available to blood banks in the United States in March following an all-out effort by the Public Health Service (PHS) and five contractor companies to meet a six-month deadline imposed a year ago by Secretary of Health and Human Services Margaret Heckler.

The performance data suggest that at least some of the concern voiced by critics of the rush effort have still not been adequately addressed. Of the 593,831 units of blood tested and reported to PHS during the four weeks beginning 22 April, 0.89 per cent tested positive in the first instance for AIDS antibody. That rate is not inconsistent with earlier estimates of the prevalence of AIDS antibody in the general population. But only 0.25 per cent of the blood samples were "repeatedly reactive" which, according to the PHS definition, means that they test positive twice in a row by the test or two times out of three if tested three times. The tests now in use all use enzyme-linked immunosorbent assays (ELISA) to detect the presence of antibody to the AIDS virus, HTLV-III/LAV. The new data cover about 70 per cent of all blood collected in the United States during that four-week period.

Although the data say nothing about the false positive rate, one of the major concerns at the outset, the large number of samples that tested positive initially but

negative when rechecked, is a worry. Test kits produced by at least two of the five companies, Abbott and Electronucleonics, showed wide variations of activity at first; Electronucleonics even had to recall from blood banks one early batch of kits on this score. Although improved quality control has done much to correct the problems, some variability apparently remains.

Meanwhile, at least some of the false positive reactions have been explained. People with certain HLA antibodies appear to react consistently positive to at least one of the tests on the market. It may be that because the test kits use virus antigen grown in human cell lines, some of the HLA antigens found on the human cell membranes are picked up in the purification of its virus protein. This problem may be eliminated when test kits derived from genetically-engineering virus antigen (grown in *Escherichia coli* rather than human cell lines) become available. These are being developed by Genentech and Centocor; clinical trials are expected to begin within two months.

So far, no data are available on how the ELISA test kits' performance compares with independent (and generally more reliable and more expensive and difficult) tests such as the Western blot. Some initial data will be presented at a conference at the National Institutes of Health on 31 July. These results should provide the first accurate reading on the false positive problem. **Stephen Budiansky**

Eureka

France puts flesh on bones

Paris

EUREKA, the French-inspired programme to unite European high-technology industry behind some concrete, profitable and advanced joint enterprises, has a public shopping list at last. Last week CESTA, the Centre d'Etudes des Systèmes et des Technologies Avancées, a public agency with an office in the very courtyard of the French ministry of research, produced a 70-page document listing five "priority action programmes" for Eureka. It is the product of two and a half months of intensive effort by the small and now somewhat fatigued interministerial Eureka group within the French government.

Until the European conference of research and foreign ministers in Paris later this month, the CESTA proposals are the nearest to a bible of exactly what Eureka is — or could be. Only "some" of the proposals are the result of recent shuttle diplomacy; the rest spring from unilateral French imagination.

The CESTA report defines five priorities: computers, networks and communications, robotics, biotechnology, and materials. And in each, it concludes with specific projects, timetables and potential European partners.

Computers dominate the proposals. In a programme dubbed "Euromatic", the Eureka group suggests that Europe should develop by 1992 a "super-Cray", capable of the 30 GigaFlops (floating-point operations) per second "required in the design of complex systems". It should be vectorial, use gallium arsenide chips (as yet unperfected technology), and could link the French companies Bull (once Honeywell-Bull) and Thomson with Siemens in West Germany. Although the market for such machines may be small, they are becoming so "essential" in certain key applications that Europe should develop a strategic independence in the technology from the present US and, shortly, Japanese suppliers.

Also under "Euromatic", the French group identifies a need to study "highly parallel" computer architectures aimed at a machine of 10 GigaFlops by 1992, via a demonstration machine 100 times less powerful by 1988. This would involve collaboration between Bull, Thomson and the German computer company GMD, which would "form the core of a broader European team including other partners (for example Britain, Italy)".

Other Euromatic projects include the development of high-capacity mass memory, starting with "giant" magnetic disks and moving on to optical disks (Bull, plus BASF and Siemens of West Germany); a software engineering centre (five companies in France, four in West Germany plus Aachen University, Philips in the Netherlands and ICL, Logica and Scicon

of Britain are suggested); artificial intelligence applied to "four precise projects" (nine companies and one university in France, four companies in Britain, Olivetti of Italy, Norsk Data of Norway and Philips and the University of Amsterdam could be involved); and there would be work on synchronous architectures, dedicated circuits and symbol processors.

The prospectus also lists projects on expert systems, multilingual access to databases, the management of large-scale industrial processes, a European microcomputer "paving the way to advances in integrated circuitry and the image processing industry, now a US monopoly", a 64-megabit dynamic memory and a European development unit for gallium arsenide technology and custom circuits.

Euromatic is by far the most specific of the five "priority actions". In robotics ("Eurobot"), France proposes the development of intelligent semi-autonomous robots for repair and maintenance in hostile environments (such as nuclear reactors), an entirely automatic agricultural tractor (Renault, Fiat and Saab could be interested), flexible-production factories (using computer-automated design and manufacture) and carbondioxide, carbonmonoxide, excimer and free-electron lasers as machining tools.

"Eurobio" involves the production of new crops and varieties for the seed industry, and the development of crops "as a means of transforming industrial processes"; and the research and development of systems for the control and regulation of biochemical processes (including biochemical reactors and novel means of drug delivery). The objective in the seed industry would be to give Europe "a leading position" on the world seed market, estimated to be worth some \$10,000–12,000 million, and some two dozen European companies, institutes and universities are identified as potential partners.

Add to these programmes "Eurocom" (communications) and "Euromat" (the development of a ceramic turbine) and you have a list of most of the high technology challenges facing not just European but all developed-world industry. So what is special about Eureka? First, the sense of urgency. Second, the fact that even the ideological French have discovered pragmatism; they say here that "nothing is fixed" about Eureka except that some practical actions should be under way by the end of this year. The key is probably government backing. "We don't expect governments to be coming with their checkbooks" to the Eureka conference later this month, they say, "but we do want to define the structure of financing". Which means it is time to say who will pay, and how.

Robert Walgate

UNESCO

Reforms now under way

Washington

A SERIOUS attempt is being made by the United Nations Educational, Scientific and Cultural Organization (UNESCO) to answer criticisms by Western nations. The executive board, meeting in Paris, has urged strengthening UNESCO's scientific and environmental activities, which are generally well thought of, but also put limits on more controversial programmes such as "Communication in the service of man". US officials seem pleasantly surprised by reports of the meeting but stress that no immediate decision to rejoin is on the cards.

Decisions taken at the marathon six-week meeting in Paris are not binding on the organization; they will however be put to the UNESCO general assembly next October in Sofia, Bulgaria, where all 260 member countries will be represented. The most pressing task has been to plan a 1986–87 biennium budget that is 25 per cent lower than the previous biennium, due to the withdrawal of the United States. Western nations (particularly Britain, which has also threatened to withdraw unless there are improvements) wanted to see the selective elimination of programmes that were judged to be either wasteful or opposed to Western interests; the Soviet Union, on the other hand, wanted to see a 25 per cent reduction across the board. So far, the West seems to have had its way.

The communications programme, for example, has been made uncontroversial by strictly limiting its more theoretical aspects, while devoting most of the funds for this topic into training of journalists. The Intergovernmental Programme on Man and the Biosphere, the International Geological Correlation Programme and the International Hydrological Programme, on the other hand, have been recommended for strengthening.

There has also been a reduction in the number of subprogrammes in the draft budget (another Western bugbear), and the whole plan has been presented in a new format that breaks with convention by being relatively easy to understand. Cost-benefit analysis is used explicitly, apparently for the first time.

The executive board has essentially ended up with a zero growth budget, with all activities beyond those that can be paid for after the 25 per cent budget reduction placed in a special category. The board suggests that similar planning should be adopted if Great Britain and Singapore do withdraw after the next assembly, as threatened. The changes so far at UNESCO, though pleasing to Western eyes, are not considered likely to make Britain change its mind.

Tim Beardsley

French telecommunications

National data network crashes

Paris

THE technical revolution in the French telecommunications system has been temporarily stopped in its tracks.

After being transformed from rustic to semidigitized in ten years, the change has been so great that it has entered the language. To be fashionable in France these days is to be "*cablé*", or "wired-up". Last year, it was "*branché*" ("plugged-in"), or even better the transposed "*chébran*".

But now and for two months, Transpac, the French and the world's most-used packet-switched data network, will be out

of bounds to individual users. Last week, private users so overloaded the system with their messages and consultations of electronic newspapers now on full-text database that the whole network crashed.

The cause is a bug in Transpac software for assembling and disassembling data packets, the groups of a few characters of a message which are given heads, tails and an address and then sent independently through the network so as to make efficient use of the gaps in other messages. "Packet assembler-disassemblers" (PADs) using this software are distributed throughout Transpac, and are designed to shut down when overloaded. At the highest levels of use reached last week, however, one PAD shut-down caused such an increase of traffic through others that they also shut down, leading to a chain-reaction which closed the whole of Transpac almost instantly.

This may have irritated the 800,000 or so home-users who now have access to Transpac through their free "Minitel" terminals, distributed by the telecommunications authority, PTT, to replace printed telephone directories. But it was disastrous for the banks, airlines and other companies with high data traffic that now rely on Transpac for business. Hence the decision by PTT to unplug the poor *cablé* public, until September, by when the Transpac bug should be sorted out.

Meanwhile the free distribution of Minitel (simple screens and keyboards) has now been suspended, but earlier projections were that the number of *Minitelistes* would more than double to 1.7 million this year, and perhaps reach 3 million by 1987. Transpac could cope with this if it were not that *Minitelistes* are not behaving as expected.

The typical "*tapeur*" at the keyboard does indeed consult the few hundred databases available — that much was expected — but, at least until the great crash, he or she spends much more time sending electronic messages to other users through systems such as "Missive", an electronic mailbox supported by PTT. And a little arithmetic shows that while 3 million times a few hundred databases is a large number of connections, 3 million squared is huge, probably too huge for even Transpac to cope with it.

That is why there is now some concern that the apparently logical French approach to create a single giant data network may not be so logical after all. For while the roads and rail seem capable, on the whole, of carrying both goods and people, it may turn out that personal data habits and the needs of industry (transferring large files with infrequent calls on a few trunk routes) are so different that quite different networks and strategies will be needed.

Robert Walgate

University of Geneva

Karl Illmensee resigns

DR Karl Illmensee, professor of biology at the University of Geneva, has resigned his post with effect from 30 September 1987 the date on which his present contract would normally expire. Illmensee's decision was submitted some days before a meeting of the professors of the University of Geneva called for 1 July at which the faculty was to have decided whether or no his appointment should be extended. The meeting would have had before it a report on the events of the past two years, during which the validity of some of Illmensee's published work has been questioned.

This latest development is probably a consequence of the report's recommendation that Illmensee's appointment should not be renewed. The report was prepared by a faculty commission appointed last February under the chairmanship of Professor R. Epstein, of the University of Geneva. Professor Illmensee had already been asked to provide a document giving his comments on the events of recent years, which is analysed in the report prepared for last week's faculty meeting. In the event, the matter was not discussed.

The Epstein report says that the quality of Illmensee as a teacher is not disputed but that there are reservations about his diffidence in sharing his techniques with collaborators. Without "wishing to give too much weight to the matter", the report also finds that Illmensee had overstated his wife's qualifications for her work as an assistant in his laboratory. Neither of these matters was taken up by the international commission looking into the more serious charges against Illmensee which reported in February last year.

Of the charges that some of Illmensee's published work is false, the report says (in respect of a series of experiments in which parthenogenetic mice were born) that there is no objective basis for proving Illmensee's observations wrong, but that it is a fair complaint that he had made no attempt to repeat the experiments.

The faculty commission makes the same complaint about Illmensee's failure to repeat the experiments involving the transplantation of nuclei into embryonic cells. Dealing with Professor Illmensee's unpublished defence, examined by the Epstein commission, the report says it does not accept his contention that he lacked the time and the means to repeat the experiments.

The commission explains its unwillingness to follow the report of the international commission by saying that that report was more damaging than its failure to find proof of deception would have suggested. The Epstein report also says that repetition of the disputed experiment was a key recommendation.

Charity for MRC

A MAJOR new institute is to be set up within the University of Oxford to apply molecular biology to medicine. The British Medical Research Council (MRC), which has been the prime mover in founding the institute for Professor David Weatherall but which has not had the cash to do so, has finally enlisted the aid of the Wolfson Foundation to the tune of £1 million. Building should take two years.

The object of the provisionally named Molecular Medicine Institute, which will be on the site of the John Radcliffe Hospital in Headington on the outskirts of Oxford, is "to create a critical mass of good science and scientists within an essentially clinical environment", says Weatherall. Each of the five or six groups within the institute will be fully integrated into the clinical school and will need to be self-sufficient in research money. MRC and Wolfson have provided the capital costs, with help from the university and the Cephalosporin Trust.

For the Wolfson Foundation, this is the first formal collaboration with any research council and the case, says Wolfson director Dr J. Black, was simply considered on its merits, which were considerable, according to Sir James Gowans, secretary to MRC. "Our collaboration is an example of the council not necessarily being resource-led. When something is important enough that it has to be done and government policy means that the resources are not available, it is a question of finding help."

Neither partner will agree that Wolfson bailed out a previously committed MRC, but Black says there has been no discussion of a continued collaboration between the two and any new request would be treated on its merits. With the present financial state of the research councils, it seems likely that they will nevertheless look more eagerly at the £7 million Wolfson dispenses each year, mainly for the capital cost of constructing new laboratories.

Peter Newmark

Swedish security

Too much free information?

Stockholm

THE Soviet Union has denied using the international interlibrary loan system to obtain sensitive defence-related information from Sweden. A spokesperson of the official Soviet news agency APN pointed out last week that, if the Soviet Union did indeed require such information, it could acquire it by a "clearer and safer method", using satellite photographs. The Swedish defence staff has, however, launched a special inquiry into possible leaks through the interlibrary loan service.

International loans from Sweden are handled by Lund University Library, one of the two Swedish copyright deposit libraries that receive a copy of every work published in Sweden. (The other is the Royal Library in Stockholm.) The Soviet Union borrows between 750 and 1,300 works from Sweden each year, mostly in the humanities. So far, only a handful of "sensitive" items have been requested, all so far from "open" unclassified literature. To refuse to send such items would run counter to Sweden's policy of open access to information, and would require the special intervention of the government. This, according to Nils Palmberg, the Lund librarian in charge of the loan service, is hardly likely at the present moment.

According to Palmberg, Lund was first

alerted to the possibility of the loan service being used for non-academic ends some three years ago, when an East German naval library requested a copy of *Marinnytt* (Marine News). This is in fact readily available from all Swedish embassies and cultural institutes, and the main puzzle about the request was why the East German navy should bother to use the loan service when they could simply have picked up a copy in East Berlin. The Lund librarians duly forwarded the copy, but felt it worthwhile to inform the Swedish defence staff and to keep a watch for further puzzling requests.

In autumn 1984, they received a request from the Soviet Union for details of naval harbours in Norrland (North Sweden) and of a hydrographical survey of the same region. Later came a request about an area of central Skania (southern Sweden) where there are several military installations. According to Bertil Lagerwall, chief press spokesman of the defence staff, the material requested in the latter case included maps, photographs and also details of new building works in the area, all of which would be of considerable interest to anyone planning an airborne invasion.

According to Palmberg, the Lund library has worked out an arrangement with the defence staff about such requests.

Lund will forward the material to the library filing the request (in the case of the Soviet Union, the Lenin Library in Moscow), and will then notify the defence staff of what has been sent. The rationale here seems to be that, since the defence staff is notified only after the material has been sent, the arrangement does not compromise Sweden's commitment to the free flow of information. There does not seem to be any overt international agreement that requests for the transfer of information should be a matter of confidence between the parties concerned, and the Swedes presumably feel that, if the motive behind the request is innocent, the person or organization filing it would have no valid objection to a third party (in this case the defence staff) being informed.

For whatever reason, both Lund and the defence staff kept quiet for several months about the agreement, which was worked out last February. It was first revealed by the *Sydsvenska Dagbladet* two weeks ago and evoked considerable public comment and concern. According to defence spokesman Lagerwall, however, the Swedish government's commitment is clear: "We cannot and will not censor open literature", he declares. **Vera Rich**

Hans-Otto Wüster

THE European thermonuclear fusion project suffered a serious blow at the end of last month, with the unexpected death of Dr Hans-Otto Wüster, the director of the JET (Joint European Torus) project. Dr Wüster (58) was a West German theoretical physicist with a PhD from the University of Köln, where he worked for seven years at the Institute of Theoretical Physics. Thereafter, he spent successive spells

at the Deutsches Elektronen-Synchrotron (DESY) at Hamburg and at CERN, Geneva, where he was deputy-director between 1971 and 1975.

Dr Wüster was appointed director of JET in 1978. During his time, the torus was commissioned successfully. Much of Dr Wüster's contribution during his spell as director was to ensure political support for JET. But the laboratory says that he will also be much missed for his strong but sensitive style of management. □

Giotto now on target for Halley's comet

THE Giotto spaceprobe, the European Space Agency's contribution to the fleet of six craft aimed at Comet Halley, was successfully launched by an Ariane 1 launcher from Kourou in French Guiana last week. The three-stage launcher placed the satellite in a geostationary transfer orbit, from which an on-board motor injected the craft into a heliocentric trajectory aimed at an encounter with Halley on 13 March next year.

One important aim of the mission is to enter the coma of the comet and, using a four-colour camera, obtain images of the nucleus, possible only from within the coma. The best resolution hoped for is 50 metres. The composition of the coma itself will be sampled by neutral and ion mass spectrometers and dust detectors, while

the electromagnetic environment will be probed by magnetometers and plasma analysers. The spacecraft is not expected to survive beyond its closest approach to the nucleus of less than 500 kilometres due to the effect of dust impacts — its relative speed is expected to be 68 kilometres per second.

These experiments will to some extent be complemented by those aboard the five other spacecraft that should encounter Halley at about the same time (see table). Giotto's instruments will be switched on in September or October. In particular, the plasma analysers will be used to sample the solar wind at the time of the encounter of the International Comet Explorer with the comet Giacobini-Zinner on 11 September.

Philip Campbell

Probes to Halley

Mission	Launch date	Encounter date	Closest approach	Nationality
Giotto	2 July 1985	13 Mar. 1986	500 km	Europe
Vega-1	15 Dec. 1984	6 Mar. 1986	10,000 km	USSR
Vega-2	21 Dec. 1984	9 Mar. 1986	10,000 km	USSR
Sakigake	8 Jan. 1985	11 Mar. 1986	7,000,000 km	Japan
Planet-A	14 Aug. 1985	8 Mar. 1986	200,000 km	Japan
International Comet Explorer	22 Dec. 1983*	28 Mar. 1986	32,000,000 km	USA/Europe

*Originally International Sun Earth Explorer-3, currently set to encounter Comet Giacobini-Zinner followed by Halley.

NERC's infrastructure defended

SIR—I wish to respond to the letter from J.S. McPherson (*Nature* 13 June, p.536) commenting inaccurately on the role of Natural Environment Research Council (NERC) HQ and NERC Scientific Services (NSS). The staff numbers he quotes are correct, but to say that "... NSS is largely administrative in composition" is wrong and grossly unfair to the 90 per cent of NSS staff who are scientists and technologists providing support for the research carried out by both institute and NERC-supported university scientists. Most of NERC's administrative staff are in the institutes.

A more than superficial perusal of NERC's annual reports for the four years 1980/81–1983/84 would reveal that in that period the "quality" of computing provided to institutes has increased by a factor of four, new and sophisticated marine

equipment has been brought into service, an image analysis facility has been brought into use (and incidentally attained a reputation sufficient to attract a Principal Investigator award from the National Aeronautics and Space Administration) and an instrumented aircraft made available for NERC-supported science. And all this has been achieved with staffing that is sensibly constant over the period.

Turning to the question of commissioned research, NSS has not, as a matter of policy, sought to sell its services in the market place. What is clear from the annual reports is that many of the contracts obtained by the institutes would not have been possible without the computing, the ships, the cartography and other support services provided by NSS and administrative services of HQ. It is regrettable that Mr McPherson does not

seem to have the text of NERC's annual report which describes the vital support role in which NSS staff are engaged.

Mr McPherson's letter contains other errors. He says that it is sad that 1,000 scientific jobs are to disappear. The NERC corporate plan published last February indicates that 900 (not 1,000) posts may be lost over the next five years. Staff reductions will be in all categories—scientific, technical and administrative—with the aim of maximizing scientific output in relation to available income. NERC would prefer not to have to reduce staff numbers but it has to be realistic, live within its means and provide its scientists with the equipment and support services which they need to be effective.

The science of sea-dumping

SIR—We wish to comment on the independent review of the practice of dumping radionuclides in the oceans, commissioned by the UK Department of the Environment, carried out by a group under F.G.T. Holliday and published last year¹. The terms of reference were to "review the scientific evidence, including the environmental implications, relevant to the safety of dumping radioactive waste at the designated North Atlantic site". The report gives a detailed description of the history of dumping and of the structure and operation of the model developed by the National Radiological Protection Board (NRPB) and the Ministry of Agriculture, Fisheries and Food (MAFF)^{2,3} which is used to assess the environmental effects of disposal.

Scientific modelling should clearly specify the model in terms of the underlying theoretical assumptions, and should indicate specific tests by which the model can be validated.

In the Holliday review, we find little discussion of the theory and none of experimental validation. The review notes that "the modelling exercise is complex and involves hundreds of man-hours of work which it has been impossible to check", but concludes that "the science being undertaken in the United Kingdom is of the highest quality. The results are published in the open literature and are openly discussed at international meetings, and this provides some safeguards on the reliability of the work."

Thus it is proposed that the ultimate guarantor of the quality of science being undertaken lies in some form of international peer review. We do not wish to comment on this process as it affects the MAFF/NRPB model as a whole but the part which concerns biological pathways.

The biological pathways sub-model is a crucial component of the whole because it concerns the potential concentration of hazardous materials which are otherwise dispersed in the ocean. In the MAFF/NRPB model the trophic level concept⁴ is used as the basis for calculating the concentration of radioactivity in marine life. Yet after the work of the International Biological Programme (1964–74) it became clear that although trophic level one (green plants) could be identified and trophic level two (herbivores) could be found in terrestrial systems, the remaining "trophic levels" could not be adequately identified⁵. This made the concept untestable and therefore suspect. Current concern about the inapplicability of the trophic level concept to aquatic ecosystems is shown by Ulanowicz and Platt⁶.

In the MAFF/NRPB model, it is assumed that the main food chain can be modelled by six trophic levels plus humans. Misleading conclusions can arise from this view that the food chain is limited in length. Materials cycle through the food web by organisms investing faeces and carcasses, creating food chains which are in trophic level terms indefinitely long^{7,8}.

Furthermore, science is surely about testing models, not simply asserting them, however authoritatively. The Holliday review illustrates several *predictions* about the effects of sea-dumping, but does not contain a single experimental result or reference. It is claimed that the model has been "adjusted" or "forced" to reproduce certain physical features of ocean dispersal, though this in itself does not imply predictive value. The final result of extremely long-range forecasting, involving release from dumped containers, oceanic dispersal and passage through food

chains, is a predicted radiation dose to humans over the next 100,000 years (peaking at 100 years). A minimum requirement for the credibility of such predictions is experimental validation in some simpler case. For example, earlier sea-dumping (1950–63) was carried out, without containment, in the English Channel; there has been the possibility of 30 years' monitoring of this more accessible release for comparison with predictions. Furthermore, much data have been collected on contamination of the Irish Sea, which could also be compared with model predictions. Are there no results of validation studies? What would the Committee on Safety in Medicines think of predictions not backed up by clinical trials?

The Holliday report does prudently recommend that sea-dumping not be resumed "until the current international reviews and the comparison of sea-dumping with land-based alternatives have been completed". It is essential that such reviews should address the two issues—the theoretical basis of the model and its experimental validation—that are absent in the current report.

Measuring the unmeasurable

After more than a century, the reality of Maxwell's displacement current has been demonstrated by direct measurement. So, too, but less conclusively, has been the Aharonov/Bohm effect.

ONE of the big surprises of Maxwell's theory of electromagnetism was his introduction of the concept of displacement current. By Maxwell's time, it was generally understood that an electrical current in a conductor would generate a magnetic field (Ampère's law applies). In modern language, the relationship is that the curl of $\mathbf{H}$, the magnetic field strength, is equal to the current, or that $\nabla \times \mathbf{H} = \mathbf{J}$, where $\mathbf{H}$ is the field and $\mathbf{J}$ the current, both of them vector quantities. Maxwell's innovation was to add to the right-hand side of the equation the rate of change with time of the electrical displacement, $\mathbf{D}$, related to the electric field strength by $\mathbf{D} = \epsilon \mathbf{E}$, where ϵ is the scalar permittivity of the material, itself related to the dielectric constant by a numerical factor depending only on the choice of units. Now the displacement current has been measured for what appears to be the first time.

None of this implies that the reality of the displacement current has been in limbo in the interval. Indeed, were it not for the displacement current, it would not be possible to deduce from Maxwell's equations that electromagnetic waves have the properties of light. Maxwell was well aware of the difficulty he was creating. Indeed, D.F. Bartlett and T.R. Corle from the University of Colorado at Boulder, who have now measured a displacement current directly (*Phys. Rev. Lett.* **55**, 59; 1985), quote him as describing as one of the "chief peculiarities" of his thesis "that the time derivative of the electric displacement must be taken into account".

The principle of the measurement is a good deal simpler than the practice. The obvious first step is to create a reasonable source of displacement current. What could be simpler than the steady increase of electrical displacement between the plates of a capacitor during the process of being charged, most simply by connecting its plates to a physical electric current?

Bartlett and Corle point out two obvious snags. First, the voltage would quickly reach the point at which there would be a spark between the capacitor plates. Second, since the obvious way of measuring the displacement current is to measure the associated magnetic field, the feasibility of the measurement is determined by the relative magnitude of the field and the sensitivity of available measuring devices. Bartlett and Corle point out that for realistic capacitors, the

expected magnitude of the magnetic field will be measured in micro-gauss.

From there, the design of the measurement is determined. The ideal of a direct-current measurement is unattainable, but a low-frequency current will do instead provided that the response-time of the ultimate measuring device is faster than the oscillation. The other requirement, that it should be possible to measure magnetic fields in the micro-gauss region, points uniquely to a SQUID (for superconducting quantum interference detector). And that, inevitably, points to the source of the complexity of the measurement, the need to contain the equipment in liquid helium.

Bartlett and Corle use a capacitor consisting of a pair of circular plates 7.6 cm in diameter and separated by 1.22 cm. The magnetic field between them is measured by a coil 1.5 mm in diameter encased in a stainless steel tube which, at liquid helium temperatures, acts as a shield against stray electric fields. The SQUID itself, based on a Josephson junction, is enclosed in a superconducting lead shield. If the arrangement were strictly symmetrical, the magnetic field induced by the displacement current, at some given phase of the driving current, would be represented by concentric circular lines of force with the field strength increasing linearly from the centre to the edge of the plates and then decreasing inversely with distance from the axis of symmetry.

At least to a first approximation, the geometry is exactly like that of the magnetic field associated with a current in a linear conductor except that, now, the current is displacement current and distributed across the whole area of the plates.

The complications are horrendous. Magnetic fields from the cables carrying the current are an obvious nuisance, if only because the measurement must be made inside a liquid-helium Dewar vessel and also inside a shield against stray magnetic fields from elsewhere. (The shield is a spherical copper vessel coated on the inside by superconducting lead/tin solder and filled with helium.) The leads carrying current to the plates are bent so that their final separate approach to the capacitor is along the axis of the arrangement, and also that the magnetic field generated by the power supply can be measured simply by rotating the measuring coil through 90 degrees. The use of an alternating power supply has the advan-

tage of allowing the phase of the oscillation of the displacement current to be determined directly.

The only surprise is the precision of the result. A plot of the field strength against distance from the centre of the plates is indeed a straight line, whose slope is determined by the small scatter of points to within three parts in 100. The measured slope differs from that calculated from the dimensions of the capacitor and the other parameters of the measurement by less than five per cent, possibly explained by the intervention of a steel tube between the two plates.

Not all physical measurements of this kind are so unsurprising, demonstrations as it were of the ingenuity of which physicists are capable. A few weeks ago (*Phys. Rev. Lett.* **54**, 2469; 1985), Giorgio Matteucci and Guilo Pozzi from the University of Bologna reported a measurement designed to verify the reality of the Aharonov/Bohm effect, the quantum phenomenon by means of which the phase of the wave function describing a particle (such as an electron) should be affected by the electromagnetic potential of an electromagnetic field even when the particles are not subjected to physical forces.

One of the first demonstrations of the effect, in which Matteucci and Pozzi also had a hand, consists in arranging that a beam of electrons will travel on either side of a superconducting tube with a magnetic field along its axis in such a way that magnetic forces do not affect the electrons. Although the apparent physical tracks of the electrons are unchanged, their phases are altered by the presence of the confined magnetic field, and interference fringes produced as a result.

What Matteucci and Pozzi have now done is to repeat the experiment with a thin platinum wire coated on one side only with a thin layer of aluminium. Because of the contact potential between the two metals, the electrons see the wire as if it were an unsymmetrical distribution of electric charge, but because the wire is thin, there is no effective force on the electrons passing on one side or the other. But yet again, because in this case the electrostatic potential is different on one side of the wire from the other, the phases change and electron interference fringes are produced. Indeed, the pattern of the fringes can be changed as the wire is rotated about its axis which will seem yet another *tour de force*.

Astronomy

An extraordinary gravitational lens and the redshift debate

from M. G. Edmunds

ONCE in a while a remarkable astronomical object is found in a fairly routine observing programme. Just such an object turned up last September during a galaxy redshift survey by the Harvard-Smithsonian Center for Astrophysics. The first published set of observations (Huchra, J. *et al.* *Astr. J.* **90**, 691; 1985) shows that right in the centre of an unremarkable redshift ($z=0.04$) spiral galaxy there sits the image of a high redshift ($z=1.7$) quasar.

There is no doubt that the quasar is of high redshift — the spectrum is almost a textbook example, showing strong hydrogen Lyman α and carbon-ion emission lines. The brightness and size of the galaxy (known by its positional coordinates as 2237+0305) are perfectly consistent with its low redshift. Yet the quasar is within about one-third of an arc of the centre, as judged on images recorded by a charged couple device solid-state detector when the terrestrial atmospheric seeing conditions were smearing point images to about two seconds of arc in size.

It is fascinating to speculate how the debate over the origin of quasar redshifts would have been affected if this object had been discovered twenty years ago, but it is unlikely that current theories of the non-cosmological origin for redshifts will have to be resurrected. Many cases are known of bright nuclei in galaxies that show quasar-like spectra (the so-called Seyfert galaxies) but whose redshifts (and by implication, distance) are the same as the host galaxy. The new object can probably be interpreted as a distant quasar, the image of which is brought towards us by the gravitational field of the nearby galaxy acting as a lens. The detection of the first gravitational lens (other than the classic deflection of light by the Sun) was reported in *Nature* in 1979 although they had been predicted by Einstein and championed by Zwicky in the 1930s. Five good cases of gravitational lensing of distant quasars are already known (for example, Turner, E.J., Ostriker, J.P. & Gott, J.R. *Astrophys. J.* **284**, 1; 1984), but these differ from 2237+0305 in that the galaxies causing the lensing are much more distant and they produce at least double quasar images.

The fun really starts when an attempt is made to estimate how likely it is that we should be able to find a system like 2237+0305. The assessment of *a posteriori* probabilities for a single object is, of course, a very subjective and uncertain task. Nevertheless, it is clear that this is a very unusual system. The chance of find-

ing such a bright quasar (approximately 17th blue magnitude) within an arc second of the centre of galaxies that have been spectroscopically surveyed would be only about one in ten thousand but, as with a conventional lens, the gravitational lens can not only bend light but also brighten the image. The difficulty, as pointed out by Huchra *et al.*, lies in the fairly large amplification factor that probably has to be invoked to increase the chance of finding such an object to, say, the few per cent level. If the quasar is not amplified, its intrinsic brightness (as implied by its redshift) must be unusually large.

Huchra *et al.* suggest that an amplification factor of 40 would give a reasonable probability of detection, and they claim that they can construct a lens model in which the required mass-to-light ratio of the galaxy is not unreasonably high (21 in solar units). But they neglect two factors in their revised probability estimate. The first is to fold into the estimate the probability of having a lens configuration that will produce such a high amplification; the configuration cannot be particularly common, since only very restricted conditions give high light amplification. The second problem is the effect of absorption by in-

terstellar matter in the galaxy through which the quasar is seen. Huchra *et al.* note that the optical continuum spectrum of the quasar appears to be highly reddened, showing a power law dependence on frequency of $\nu^{-3.5}$, compared with a typical $\nu^{-0.6}$ for most quasars. While it is possible that the object has an intrinsically steep spectrum, it is not difficult to show that the change in continuum slope from a typical value implies three magnitudes of extinction and hence requires yet another factor of 20 in amplification of the background object.

These two problems seem to make the detection probability dwindle too much for comfort, but it would be wise to wait for more detailed lens models and further observations before passing judgement. Higher spectral resolution observations reveal whether the quasar shows any sign of interstellar absorption features, such as calcium H and K lines and the sodium D line, which would give an independent estimate of extinction. Observations at deeper and higher spatial resolution, which will require seeing conditions of about half an arc second, may resolve the central image into subsidiary images which would allow better modelling of the lensing. The lensing explanation would, of course, be established were spectroscopic evidence that each of the split components had the same redshift to become available — an excellent project for the Space Telescope when it is launched. □

Protein structure

A new twist for hairpin turns

from Jane S. Richardson

In protein conformation, the tight turn^{1,2} is considered the classic, neat solution for connecting two antiparallel strands of beta-sheet. However, in the course of surveying and cataloguing short beta-hairpin connections (see page 170 of this issue³), Lynn Sibanda and Janet Thornton have unexpectedly found that this apparently obvious combination is not so well matched after all.

Beginning with the chiral alpha-carbons of natural L-amino acids, conformational features at all levels of protein structure show strong handedness preferences such as the right-handed alpha-helix, the right-handed twist of beta-sheet (see figure and ref. 4), and the right-handedness of beta-alpha-beta crossover connections^{5,6}. Tight turns also have a handedness, as they are not really planar as often drawn but have a pronounced dihedral angle defined by the four successive alpha-carbons. In the most common turn, termed Type I, that dihedral angle is approximately -45° (ref. 7). There is a mirror-image version of the

Type I turn (called Type I') which has a $+45^\circ$ dihedral angle, but it is very rare because it puts the side-chain beta-carbons uncomfortably close to the backbone and so only works well with glycine.

Sibanda and Thornton³ now show conformational preferences for each size category of beta-hairpins. For the shortest hairpins (with only two residues connecting the last hydrogen-bonded pair in the beta-strands) they find only 4 Type I turns but 15 Type I'. This is quite startling, as it reverses the overall occurrence statistics by a factor of about 40. The unusual circumstance responsible for that reversal is presumably a strong interaction between the twist of the beta-sheet and the twist of the turn. Those twists match perfectly for Type I' but fight each other for Type I, as illustrated in the figure.

One can imagine this built-in conflict as resolvable in two distinct ways during the folding of a real protein structure. If a beta-hairpin initially formed with its turn in the standard Type I geometry, the beta-

sheet twist would put a torque on the turn. In some cases the outcome could be breakage of the one or two hydrogen bonds closest to the turn, usually forming a kink in that part of the hairpin with the result that it would be classified by Sibanda and Thornton as a four-residue rather than a two-residue beta-hairpin. This outcome is more likely when the turn side chains are bulky, and is probably the only way to accommodate a proline. In other cases the torque might produce a shift of ϕ and ψ conformational angles over to values suitable for a different turn type. Types I and I' probably do not interconvert, as their ϕ and ψ angles differ by an average of 120° . However, there is another mirror-image pair of turn types available called II and II'. Type I could probably be converted to II' while Type II could switch to I', greatly improving the match to the beta-sheet twist in both cases. This sort of conversion should be much easier if one or both turn residues were glycine, and indeed 21 of the 25 short Type I' or Type II' beta-hairpins were found to contain at least one glycine.

The ubiquity of alpha-helices in proteins partly results from the fact that the local and long-range conformational preferences coincide. For beta-hairpins, however, we are now led to imagine the protein as arbitrating uneasily between the conflicting demands made by the turn residues and the beta-strand residues. □

Geochemistry

Ocean islands – plums or plumes?

from Shen-su Sun

THE 'hotspot' model has played an important role in modern geological sciences ever since it was first proposed, more than 20 years ago, to explain volcanic activity in oceanic island chains, most notably the Hawaiian Islands. Morgan¹ suggested that hotspot volcanism is caused by melting of material that is welling up from deep in the mantle. Despite much research, leading to several competing models, a precise location for the sources of the zones of upwelling remains elusive. The situation presents a challenge to geochemists: can we develop tests to discriminate between the various models? In two recent papers Schilling and co-workers have addressed this question and provided firm support for the mantle plume model^{2,3}.

The arguments have centred on the geometric relationship between the mantle sources for hotspot volcanism and the sources for mid-ocean ridge basalts (MORB). The consensus view is that the source for MORB is located within the convecting upper mantle. The zones of upwelling judged responsible for hotspots, which Schilling *et al.* now regard as 'mantle plumes', seem to be essentially continuous and stationary in the convecting mantle with respect to the overlying lithosphere on a timescale of 100 million years^{4,5}.

Mantle plumes, according to Schilling *et al.*, are derived from 'fertile' regions capable of generating large quantities of basalt and located at depths greater than the depleted sources of MORB. Geochemical study of basalts from the Faroes-Iceland region led Schilling and Nygaard⁶ to suggest that upwelling of the plume material is cyclic on a timescale of 10–20 million years and in the form of 'blobs' instead of a continuous column. Alternative models include melting at the top of the upper mantle induced by propagating fractures caused by thermal and membrane stresses in the oceanic lithosphere⁷ or selective melting of fertile mantle domains of various sizes randomly embedded in the convecting upper mantle. The latter has been referred to as the 'raisin' or 'plum-pudding' model.

It has been known for some time that MORB dredged from 'normal' ridge segments well away from any hotspots is geochemically grossly depleted. Such depletion is characterized by low abundances of large-ion lithophile elements such as K, Rb, Th, U, Ba and Cs, together with low ratios of La / Sm and Nb / Zr, a high ratio of $^{143}\text{Nd} / ^{144}\text{Nd}$, a $^{87}\text{Sr} / ^{86}\text{Sr}$ ratio of about 0.7025 and a $^{206}\text{Pb} / ^{234}\text{Pb}$ ratio of about 18.0. In contrast, hotspot-related oceanic basalts are variably enriched in large-ion lithophile

elements and generally have higher $^{87}\text{Sr} / ^{86}\text{Sr}$, $^{206}\text{Pb} / ^{234}\text{Pb}$ and lower $^{143}\text{Nd} / ^{144}\text{Nd}$ ratios. Basalts dredged from mid-ocean ridges near hotspots show a mixing character between these two types of source. This leads Schilling *et al.* to suggest that excess plume material rising beneath the ocean island is channelled along the mid-ocean ridge axis where it interacts with the 'normal' MORB². An ideal area for testing this channelling theory is in the South Atlantic where the ocean islands of St Helena, Gough and Tristan da Cunha lie 400–800 km east of the ridge axis. The ridge axis in the South Atlantic has been drifting westward relative to the hotspots at a rate of 1–2 cm per year for 25 million years. By detecting the geochemical effect of the plume material on the mid-ocean ridge system in MORB from the rift valley at latitudes corresponding to the extension of the hotspot traces, Schilling *et al.* provide convincing support for their hypothesis.

Consideration of the geometrical relationship between MORB and hotspot sources provides further evidence for the authors' theories. As shown in the figure, models 1 and 2, which combine the mantle plume model with passive feeding of the MORB source, can account for the observations. But as Schilling *et al.* point out, the chances that the plum-pudding model (model 3 of the figure) could generate the trace-element effect observed in MORB from part of ridge axes immediately opposite the tracks of near-ridge hotspots, and not elsewhere, must be very small. Additional support for the plume model

Schematic representation of mantle flow-plate motion models. 'White' volcanoes are derived from 'white blobs'; 'black' volcanoes from 'black blobs'. Modified from ref. 2.

comes from the observation that hotspot traces cross over ridge axes such as the Ninety east Ridge and Kerguelen Island in the Indian ocean and several hotspots in the Atlantic². If the hotspots were generated by fracture propagation with their magma sources heterogeneously distributed at shallow levels in the convecting mantle, then the cross-over process should have erased all memory of thermal perturbation related to hotspots and, indeed, the hotspots themselves. Consequently, their source must be deeper than the immediate source region for MORB.

One possible snag with the proposals of Schilling *et al.* is that they require that divergent convective motion is inoperative under the ridge axis. It is not clear that this is the case. The possibility that advective overflow of the hot buoyant plume material along the connecting channel to the ridge axis could have been decoupled from the underlying convective upper mantle deserves further evaluation.

A by-product of plume material intrusion and entrainment in the depleted upper mantle is the creation of local heterogeneities — as envisaged in the plum-pudding type models. Consequently, plume and plum-pudding models need not be mutually exclusive in a dynamic mantle, which could very well satisfy geochemical and isotopic data observed in many isolated seamounts with no obvious connection to long-lived hotspot traces. That the Pb and Sr isotope compositions of basalts from Gough, Tristan da Cunha, Kerguelen Island and St Helena are unusual compared with most hotspots, offers the change of further quantitative evaluation of the plume-ridge interaction and the

plum-pudding formation process.

Finally, what about the source and cause of mantle plumes? Several models have been proposed, most of which are related to the fate of the subducted oceanic lithosphere³. If this is not smeared out by viscous flows and distributed back into the convecting upper mantle to generate ubiquitous heterogeneity, it could congregate into a distinct density layer, perhaps at the base of the upper mantle (about 650 km deep). Thermal disturbances in the deep mantle could then trigger density instabilities in this layer, inducing partial melting and plume upwelling. Such a subduction-revival cycle could take hundreds of millions of years. A spectrum ranging from pure 'chemical' to 'thermal' plumes could thus be generated according to the degree of mixing between the material derived from the subducted lithosphere and the depleted upper mantle⁴.

It is conceivable that a large plume within the slowly convecting mantle might be sufficiently robust to reach this deep layer where it could turn into a plume simply by adding an 'e' — where the 'e' stands for energy! □

Endangered species

Salvaging single-sex populations

from Jared M. Diamond

LAST year I reported in these columns on the narrow escape from extinction of the Chatham Island Black Robin, which had declined to five males and two females (*Nature* 309, 308; 1984). The rescue of the Dusky Seaside Sparrow (*Ammospiza maritima nigrescens*) poses a greater challenge, because the three surviving individuals are all males. A programme to salvage its gene pool, directed by Charles Cook and Herbert Kale (Kale, H. W. *Bird Conservation* 1, 128; 1983 and *Florida Naturalist* 57(4), 9; 1984), illustrates both the problems encountered in such efforts and the debates over whether the efforts should be undertaken at all.

The Dusky Seaside Sparrow, a local subspecies sometimes considered to be a full species, was formerly abundant in marshes on the east coast of Florida, but in the 1960s, most of its habitat was destroyed. During the 1970s the US Fish and

Wildlife Service (USFWS) spent five million dollars to save the sparrow by buying its remaining habitat, now the St John's National Wildlife Refuge. This programme failed because of the continuing destruction of the refuge habitat by fires and drainage. The last record of a female bird was in 1976. Finally, in 1979, five of the last six surviving males were brought into captivity for their protection.

At that stage, the only chance to salvage genes of the sparrow was to breed Dusky males first with females of the related Scott's Seaside Sparrow and then with successive generations of resulting hybrid female offspring. Five such crosses would yield birds that were, progressively, 50, 75, 87.5, 93.8 and 96.9 per cent Dusky. Once a large enough flock of 96.9 per cent hybrids had been obtained, some could then be re-established in natural Dusky habitat. To this end, a Dusky male and a

Scott's female were mated experimentally in 1980, yielding four 50 per cent Dusky hybrids.

For the next two years, while the last Dusky males grew older, USFWS refused not only to fund but even to permit the hybridization programme. When the service finally granted permission in 1983, funds still had to be obtained from private sources: these were given by Walt Disney World, Florida Audubon Society, International Council for Bird Preservation and Wildlife Preservation Trust. In 1983, one 75 per cent Dusky female was produced, followed in 1984 by another 75 per cent chick (not yet sexed) plus a 87.5 per cent chick that, tragically, broke its neck. As the 1985 breeding season approaches, the fate of the Dusky gene pool depends on the three surviving males approaching 10 years of age, which is very old for small temperate-zone songbirds.

This captive breeding programme illustrates vividly two biological difficulties: that small populations are very susceptible to accidents (such as the death of the chick), and that old birds are poor breeding stock. One of the old males has been unsuccessful at wooing females, and another yielded only infertile eggs. In 1984, the 50 per cent female produced eight clutches and twenty eggs, of which only five hatched and one survived. Thus, a practical message for salvage programmes is to start when there are many youthful survivors, rather than waiting until it is too late, or nearly so.

The broader question raised by the back-crossing programme is whether it is even worth attempting. Some of the objections raised by USFWS were baseless: that hybridization would dilute the Dusky gene pool (but it was doomed otherwise); that hybrids might not be fertile (they are); and that hybrids might not resemble the Dusky Seaside Sparrow (they do). However, another objection raises a significant issue: the Service neither wants to spend money on restoring Dusky habitat for eventual releases, nor on saving hybrids. (In the words of one official, "Legally, a 98.4 per cent Dusky isn't a Dusky".) Many biologists similarly object to captive breeding programmes on single species, when money for habitat preservation that could save many species is so scarce. However, the number of species for which captive breeding or back-crossing offers the sole chance of survival is growing rapidly and the current programme on the California Condor would have been impossible without the experience gained from similar programmes with the Andean Condor and Peregrine Falcon. Thus, although the Dusky Seaside Sparrow is just a small drab bird, the lessons being learned with it now will surely have wider application. □

Gene regulation

Controlling roles for snurps

from Phil Turner

SEVERAL recent publications point to the possibility that small nuclear ribonucleoprotein particles, or snurps, may play much more important roles in the processes of gene regulation than previously thought. Over the past year or so, proof has been obtained of the involvement of snurps in the removal of introns (splicing) and the production of correct 3' ends from primary gene transcripts (pre-messenger RNA). Since there are now many examples both of alternative splicing pathways, which result in more than one mature mRNA species from a single pre-mRNA, and of the differential use of alternative poly(A) sites, snurps may not simply perform these processing steps but may be used to choose between the alternatives. If so, their action would constitute an important form of post-transcriptional control of gene expression.

Our best understanding of the biochemical reactions performed by snurps comes from the work of Max Birnstiel's group in Zurich on the involvement of the U7 snurp in the production of correct 3' ends of histone mRNA in the sea urchin. Based on the complementary DNA sequence of the sea urchin U7 RNA, Strub *et al.*¹ have suggested a model in which the 5' end of the U7 RNA hybridizes with two conserved regions at the 3' end of the histone pre-mRNA (see figure). The conserved regions in the pre-mRNA are the hairpin structure that is found immediately upstream of the 3' end of the histone mRNA in most species and a sequence (CAAGAAAGA) that occurs six nucleotides downstream of the actual 3' end of the mature mRNA. (The latter sequence seems to exist in an altered form in higher eukaryotes², possibly explaining the fortuitous requirement of the sea urchin U7 RNA for correct processing of the sea urchin histone H3 mRNA in frog oocytes³.) In this model the U7 RNA linearizes the hairpin structure by forming base pairs with 13 out of the 16 nucleotides in the hairpin. It also forms 6 base pairs with the CAAGAAAGA sequence and in doing so the region of the histone pre-mRNA between the conserved regions forms a small loop which is presumed to facilitate the endonucleolytic cleavage that produces the mature 3' end¹.

Support for this model comes both from the previous observation that the hairpin structure is absolutely required for correct 3' end production⁴ and from experiments recently reported in *The EMBO Journal*. Using a series of deletion and insertion mutants of the sea urchin histone H3 gene, Georgiev and Birnstiel⁵ have shown that the CAAGAAAGA sequence is essential for pre-mRNA processing. These experi-

ments also demonstrate that the topology of the two conserved regions is important; the insertion of only six nucleotides between them abolishes processing. In addition, for the rate of processing to be maximal, the pre-mRNA must contain at its 3' end 50–80 nucleotides with no special sequence requirement⁶ and also a 5' cap structure⁷.

This picture of the processing of histone pre-mRNA by the U7 snurp has a number of similarities to the generation of the 3' end of other gene transcripts by post-transcriptional cleavage which, however, is then followed by the addition of a poly(A) tail. In an increasing number of mRNAs, additional sequences downstream of the essential AAUAAA sequence are found to be required for 3' end formation⁸, with the poly(A) addition site falling between two required sequences. An analysis of 61 vertebrate poly(A) sites⁹ demonstrates that two classes can be described, depend-

Proposed role of U7 snurp in converting histone pre-mRNA into processed histone mRNA. Small arrow indicates the point of cleavage that generates the 3'-end of the processed histone mRNA. The two conserved sequence elements are shown in large letters. The histone coding region is the interrupted hatched line.

ing on whether the pentanucleotide CAYUG is immediately upstream or downstream of the site of poly(A) addition. Possible base-pair interactions of both these classes of poly(A) site with the U4 RNA sequence, which are similar to the suggested pairing of U7 RNA and histone pre-mRNA, have been noted⁹. Further evidence that snurps are involved in 3' processing of some polyadenylated RNAs comes from the evidence that certain antisera against snurps inhibit polyadenylation *in vitro*¹⁰.

The U4 and U6 RNAs form part of a single ribonucleoprotein particle as a result of intermolecular base pairing^{11,12} (which explains why U6 seems to react with the so-called Sm antisera despite lacking the sequence by which the Sm antigen is thought to bind). If the U4/U6 complex is involved in poly(A) processing then it must be dissociated in part for the U4 RNA to interact with the poly(A) site as proposed⁹. In this connection, the U7

RNA also seems to lack the sequence that would explain its precipitation with Sm antisera¹. Gel analysis of U7 RNA purified from a 12S snurp showed the presence of an RNA molecule about 100 nucleotides in length¹³. U5 RNA is approximately 100 nucleotides long and shares an 8-nucleotide homology with U7. The significance of these observations is not clear, but it is possible that certain snurps interact with each other during their processing activities.

Since the initial suggestion, based on sequence complementarity, that the U1 snurp might be involved in intron removal¹⁴, much supporting evidence has been obtained. Recently, Kramer *et al.*¹⁵ have shown that the ability of nuclear extracts of HeLa cells to splice pre-mRNA can be abolished by prior treatment of the extracts with human autoimmune antibodies and that the inhibition can be prevented by prior saturation of the antibodies with purified (U-type) snurps. In addition, splicing can be inhibited by removal of eight nucleotides from the 5' end of the U1 RNA of the snurp.

In a complementary series of experiments Tatei *et al.*¹⁶ have shown that U1 snurp fractions bind to synthetic single-stranded DNA 5' or 3' splice sequences or RNA transcripts derived from them, whereas U2 snurps do not. Further purification of the U1 snurp resulted in preferential loss of binding to 3' splice sites suggesting that additional components are required for U1 snurps to bind to both splice sites.

In vitro splicing of pre-mRNAs is most efficient if they possess capped 5' ends, the splicing reaction being inhibited by cap analogues as long as they are added no later than the start of the incubation¹⁷. The appearance of the spliced product, which occurs via the formation of a lariat or tailed-circular molecule (reviewed in refs 18 and 19), is only seen after a lag period of 30–45 minutes²⁰. Lag periods have also been observed for polyadenylation *in vitro*²⁰ and for histone maturation *in vivo*; the latter is cap dependent⁴. The existence of a lag period in these processing events could indicate a requirement for assembly of pre-mRNA into a suitable RNA-protein complex or a requirement for a scanning process to ensure that only appropriate 5' and 3' splice sites come together. To test whether a scanning process is involved, oligonucleotides or antisense RNA transcripts that can form hybrids with introns or exons could be introduced into processing systems; scanning might be inhibited by short double-stranded regions, whereas folding of large introns to produce lariats should not be inhibited.

The argument usually put forward against a simple scanning model is that alternative pre-mRNA splicing pathways have frequently been observed, sometimes within a single cell type²¹ and sometimes with tissue specificity²². But scanning could still be operative if, before the

commitment to splicing is taken, certain criteria at the 3' side of an intron have to be fulfilled. These criteria would include the existence of a 3' splice-site consensus sequence and, in some cases, the existence of a branch-point sequence or functional equivalent in the appropriate position²³. For some introns, the adoption of specific secondary structures could be an added criterion²⁴, and the presence of another snurp particle bound to, or aiding recognition of, the 3' splice site may also be required^{16,19}. If the various criteria were not met, splicing would not take place and the criteria would then be reassessed at the next 3' splice site. In this way certain exons could be 'jumped' or processed out. This could occur stochastically within one cell type if two alternative secondary structures were possible for that intron but only one fulfilled the criteria, or if two types of 3' snurp particles were present but only one had the necessary affinity for particular 3' splice sites to allow splicing. In such a model it would be possible for the criteria for 3' splicing to be met by a different species of pre-mRNA molecule, giving rise to the process of 'trans-splicing'. With the processing systems now available we may not have long to wait to see if this kind of reaction can occur.

If there is scanning, pre-mRNAs that undergo mutually exclusive alternative splicing, such as the troponin T pre-mRNA²², ought not to be spliced *in vitro* following pre-hybridization to an oligonucleotide complementary to an exon sequence that is usually processed out. This is readily testable. In addition, for those pre-mRNAs which exhibit alternative splicing certain parts of the precursor sequence, intron or exon, must specify in some way whether or not the 3' splice site is to be used. This could be achieved through alternative secondary structures or by differential affinities for two classes of snurps, but for tissue-specific alternative splicing it is best explained by the binding of other protein factors, which influence whether a 3' splice site will be used. In this connection it has been reported that preloading the frog oocyte nucleus with certain ribosomal proteins can alter the processing of the pre-mRNA encoding that protein (I. Bozzoni, 10th EMBO Symposium, 1984). The processing of SV40 RNA in frog oocytes also suggests that different splice sites in the same pre-mRNA have dissimilar interactions with various snurp particulars during splicing²⁵.

Similar types of regulation can be envisaged where differential use of poly(A) sites occurs. In some cases the differential use of two sites may simply reflect the relative probability of the removal of an intron that contains a poly(A) site and the subsequent use of a distal site, rather than the occurrence of processing and polyadenylation at the poly(A) site in the intron, which would remove subsequent exons from the product. Which of these two pathways was used could reflect the

endogenous levels of the different snurp activities involved. This could explain the alternative use of poly(A) sites in the immunoglobulin μ gene transcripts²⁶. Tissue-specific use of alternative poly(A) sites would require additional trans-acting factors, which would presumably recognize sequence signals in the pre-mRNA concerned, and would vary the processing pathway taken by the snurp.

If snurps do perform some of these regulatory roles (with or without the assistance of other factors), then one would expect some classes of snurps to exhibit differential regulation, as has recently been noted for U1 snurps in *Xenopus*²⁷.

In conclusion, evidence is mounting that snurp-mediated processing events are important post-transcriptional regulatory steps for some pre-mRNA types. Perhaps when the functions of U2 and U5 snurps are finally worked out we shall have a better appreciation of the subtleties of this regulation. □

Climatology

Impact of extreme events

from T. M. L. Wigley

BECAUSE the impact of climatic change is so dependent on the society that is affected, it is difficult to isolate unifying features or rules by which to assess the impact. We can be fairly sure that the early stages of any worldwide change, such as warming caused by the CO₂ greenhouse effect, will not be a problem because socio-economic factors — diversity in agriculture, international trade and planned water resources — will act as buffers to change. Impacts accrue, however, not so much from slow fluctuations in the mean, but from the tails of distribution, from extreme events. In many cases, an extreme can be defined as an event where a climatic variable exceeds some absolute threshold. This has led to the concept of climatic marginality, first studied in detail by M. L. Parry¹ and now taken further by Parry and T. R. Carter².

In analysing the effects of the severe weather of the Little Ice Age on the peoples of southeastern Scotland, Parry originally made three points; that, on the margins of agricultural viability (through cold or dryness), extreme events must occur more frequently; that the frequency of such events might change dramatically as a result of even a small change in the mean climate; and that the probability of two successive extremes is even more sensitive to small changes in the mean. The importance of successive extremes lies in their amplified cumulative impact. A single extreme may be easy to withstand but, if buffer stocks are depleted by one bad season, a second in succession could be far more devastating.

The simple probabilistic aspects of

Phil Turner is in the Department of Biochemistry, University of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK.

Parry's arguments are easy to demonstrate. Under a stable climate, an extreme event may be assumed to occur when, say, climate variable X falls below some critical threshold X_c . The probability of such an event is given by the area under the tail of the distribution where X is less than X_c . If we now shift the mean of the distribution towards X_c , this area will increase in a highly non-linear way, as shown in the figure. A change in the mean by only one standard deviation would make an extreme event that had been expected only once every twenty years become five times as frequently expected, and an event previously expected once a century would be expected every eleven years. For example, if the annual mean precipitation of about 920 mm over England and Wales fell by 100 mm (about 0.9 standard deviation) a drought that was expected one year in a hundred ($P_1 = 0.01$) would become roughly 7.5 times more frequently expected ($P_2/P_1 = 7.5$, point A in the figure). A doubling of CO₂ concentration is likely to produce changes of more than one standard deviation in both precipitation and temperature in many parts of the globe.

Changes in the probability of two successive extremes are even larger: two successive 1-in-20 year events go from being most unlikely (a return period of 400 years) to being quite probable (a return period of only 16 years). Of course, these are highly idealized calculations, but they do serve to emphasize the importance of extremes and provide a conceptual framework for estimating the impacts of future climatic change. Changes in both

Sensitivity of the frequency of extreme events to changes in the mean (based on an assumed normal distribution and constant standard deviation). Abscissa shows the change in mean (ΔX) as a multiple of standard deviation (s); ordinate shows the resulting change in the probability of extreme events with initial probabilities (P_1) of 0.1, 0.05 and 0.01.

inter-annual variability and in year-to-year persistence of climate may either amplify or dampen these influences of a changing mean. These ideas have been developed in more detail by Parry and Carter².

This focus on variability and extremes has been examined for shorter timescales by L. O. Mearns, R. W. Katz and S. H. Schneider³. Noting that some crops are sensitive to temperature extremes (for example, a few consecutive days over 95°F can significantly reduce corn yields in the United States) they have used an autoregressive model to calculate the effects of a changed mean on the

frequency of daily extremes, specifically daily maxima over 95°F. The stochastic simulation approach they use is essentially that used in stochastic hydrology, where the technique has been developed to a high degree over the past 20 years. (At least one study⁴ has considered the impact of climatic change on water resources in this way, although the results were rather inconclusive.) Echoing Parry's conclusion, Mearns *et al.* find that the relationship between changes in mean temperature and changes in the probability of daily extremes is highly non-linear, and that small changes in the mean can sometimes produce relatively large changes in the probabilities of certain events. Their results are sensitive to assumptions regarding changes in variability and changes in day-to-day autocorrelation, but the qualitative conclusions hold even if these parameters are varied.

Changes in the frequency of extreme high (or low) temperatures are of importance not only to agriculture but also, for example, to energy demand and human mortality, so this type of analysis can provide broad insights into the way that climatic change may affect society. It also opens up new avenues for multi-disciplinary research into climate impact assessment. □

Neuropharmacology

Super-potent serotonin blockers

from Leslie L. Iversen

STARTING ON page 126 of this issue, B. P. Richardson and colleagues from Sandoz describe the discovery of a novel class of serotonin antagonists which offer new insights into the pharmacology of this biologically active indolamine¹. The new drugs are among the most potent of any type ever described: some act at concentrations as low as 10^{-14} M. The compounds, which bear a structural resemblance to both serotonin and cocaine are indoletranyls or homotropanyls esters. They specifically block the ability of serotonin to excite various peripheral nerves in the autonomic and sensory nervous systems. Furthermore, different compounds in the new series show wide variations in their potency for antagonizing the effects of serotonin on different types of peripheral nerve, suggesting that neural receptors for serotonin (termed M-receptors) comprise a variety of distinct

pharmacological sub-classes.

One important role of the M-receptors may be to mediate the painful effects of serotonin released during injury or vascular spasm, by triggering activity in the endings of pain fibres. One of the new antagonists, ICS 205-930, can block the painful effects of serotonin administered locally to human skin and may prove useful in controlling pain in migraine sufferers.

Serotonin (5-hydroxytryptamine, 5-HT) has been known for some forty years, and its pharmacological actions on various tissues have been studied intensively. Gaddum was first to show that the actions of serotonin on some smooth muscles can be blocked by the powerful hallucinogen D-lysergic acid diethylamide (D-LSD). A number of different receptor classes for serotonin has been suggested in peripheral tissues and in brain. Gaddum and Picarelli² showed that serotonin con-

100 years ago

THE COMET OF 1472. — M. Celoria of Milan has discussed the elements of the last comet observed by Toscanelli, which is the celebrated one of 1472, also observed by Regiomontanus, whose description of its path in the heavens enabled Halley to make a rough approximation to its orbit, as he states in his "Synopsis of Cometary Astronomy." The Chinese account of the comet's track contained in the supplement to the great collection of Ma T'wan Lin, of which Edouard Biot published a translation in the appendix to the "Connaissance de Temps" for 1846, enabled Langer to make a further calculation of the orbit, though the somewhat full description of the comet's course amongst the stars is unfortunately very deficient in dates.

From *Nature* 32 231, 9 July 1885

tracts the intestine by two different mechanisms: a direct action on smooth muscle, mediated by D-receptors, and an indirect action on autonomic nerves to stimulate acetylcholine release, mediated by M-receptors on neurones. More recently, radioligand binding studies have also revealed two classes of binding sites, termed 5-HT₁ and 5-HT₂. The 5-HT₁ sites are identified by high affinity binding of serotonin in brain and may mediate contractile responses in some peripheral tissues, particularly stomach. The 5-HT₂ sites, which may correspond to the D-receptors, are found in both brain and periphery; they mediate contractile responses in peripheral blood vessels and aggregation responses of blood platelets to serotonin³. These sites are potentially blocked by classical serotonin antagonists: cyproheptadine, cinanserin, methergoline, methysergide and ketanserin; in brain they are identified by using radiolabelled ketanserin as a ligand⁴. Both classes are potentially blocked by D-LSD, although it is not known whether this explains LSD's unique psychopharmacology. Neither class is sensitive to the new Sandoz analogues, which appear to be specific for the neural M-receptors.

The development of the new compounds stems in part from the discovery by J. R. Fozard⁵, that cocaine is a weak but selective antagonist of neural responses to serotonin. Fozard and his colleagues at the Merrell Dow laboratories in Strasbourg used this discovery to develop a series of selective serotonin antagonists modelled on the cocaine structure. One of these, MDL 72222, reported last year⁶,

has a selectivity similar to the antagonists now described although it is considerably less potent. The Sandoz researchers first synthesized analogues of serotonin and discovered compounds that selectively mimicked its effects on neurones or on smooth muscle. This knowledge was used to synthesize antagonists with selective action on neurones in which the serotonin side-chain nitrogen is incorporated in a tropane ring, as in cocaine (see figure).

Interest in serotonin pharmacology has been particularly strong in the past few years. New generations of antidepressant agents are emerging that act by inhibiting the re-uptake of serotonin after its release from synaptic terminals in brain, thus enhancing its synaptic actions⁷. It has also been reported recently that novel anti-anxiety drugs of the buspirone type may act by selective stimulation of serotonin receptors in brain, although the precise category of sites involved remains unclear⁸. Receptors for serotonin of the

type that are blocked by the new antagonists have not yet been identified in the central nervous system but their presence there would not be surprising.

As so often in pharmacology, the discovery of novel drugs with selective antagonist actions will undoubtedly allow rapid progress to be made in defining the occurrence and functional significance of a hitherto obscure class of monoamine receptors. □

Surface structure

X-ray reflection from liquids

from Stuart A. Rice

IN AN important paper in *Physical Review Letters*, A. Braslau *et al.* report measurements of the surface roughness of water deduced from the scattering of X rays reflected from the surface¹. To do so, they have introduced a new way to interpret the reflectivity data. This and related advances are beginning to revolutionize the understanding of liquid surfaces.

For two decades there has been a steady stream of improvements in the scope and sensitivity of techniques with which to study the atomic and electronic structures of surfaces. Many of these techniques use electrons as probes, or detect electrons, or both. Unfortunately, because electrons interact very strongly with the atomic charge distribution, the interpretation of electron-scattering data usually requires removal of the contributions to the signal from multiple scattering processes, which cannot at present be carried out for liquid surfaces. Unlike electrons, X rays are weakly scattered by the atomic charge distribution, and two X-ray techniques have recently been introduced to study surfaces: X-ray reflectivity as a function of angle of incidence, and grazing incidence X-ray diffraction. Both can be used to study liquids as well as solids.

That X rays will be totally reflected from a condensed medium if the angle of incidence is less than some critical value was predicted and first demonstrated by A.H. Compton in the 1920s². The thrust of the work in the following decade was concerned with the determination of the refractive index of matter at X-ray frequencies, assuming the sample to be homogeneous up to a planar surface, treated as a geometrical discontinuity. It was

not until 1954 that L.G. Parratt suggested inverting the analysis and interpreting X-ray reflectivity as a function of angle of incidence via models of the inhomogeneous surface-density distribution³. This suggestion lay dormant for twenty years, until B. C. Lu and S. A. Rice⁴ adapted it to provide information about the surface structure of liquid mercury. Other applications^{5,6} are rare.

X-ray reflectivity as a function of angle of incidence is sensitive to the distribution of density perpendicular to the surface; the greater the range of incident angles for which measurements can be made, the more accurate will be the inferences drawn about the surface density profile. The dynamic range required for such experiments is large — of the order of 10^7 to 10^8 — so synchrotrons are the favoured X-ray sources. The data can be interpreted by two means. In one, a model of the surface-density distribution is assumed and the predicted X-ray reflectivity is compared with that observed. Alternatively, the data can be interpreted in terms of some model-independent parameter that is characteristic of the density profile.

It is the second means of interpretation that has been introduced by Braslau *et al.* They show that the reflectivity data they obtain can be interpreted in terms of the mean square roughness of the surface without prescribing the molecular mechanism by which the roughness is generated. The value they obtain for this measure of the surface density profile is $3.24 \pm 0.05 \text{ \AA}$. A molecular dynamics simulation of a rigid charge distribution model of water⁷ shows that the density

falls smoothly through the liquid-vapour interface with a characteristic width of $3.56 \text{ \AA}$; the deviation between these values provides one measure of the inadequacy of the model potential used in the molecular dynamics simulation.

As expected, total external reflection of X rays is accompanied by fluorescence and, very recently, this has been exploited to study the properties of solid and liquid surfaces. Smirnov⁸ has shown that measurement of the fluorescence intensity as a function of angle of incidence of the exciting X rays can be used to infer the density distribution perpendicular to the surface — in his case, for a film of germanium deposited on glass. In an independent development, Bloch *et al.*⁹ have used the same kind of measurement to infer the concentration profile of a dissolved polymer in the solution-vapour interface.

To date, the only reported application of grazing incidence X-ray diffraction to a liquid is by J. Als-Nielsen and P. S. Pershan¹⁰ who measured the interplanar spacing perpendicular to the surface of a smectic-A liquid crystal. The interpretation of the X-ray diffraction pattern in terms of the in-plane distribution of molecules in a liquid-vapour interface is more difficult than for a solid, because removal of the contribution to the X-ray scattering from atoms below the surface requires knowledge of their distribution as a function of density. Whereas the atomic distribution in a crystal substrate is substantially the same up to the outermost plane of atoms, the variation in distribution in the 2–3-atom thick, inhomogeneous liquid-vapour interface is important. Nevertheless, guided by computer simulations, it should be possible to obtain useful information about the in-plane distribution of atoms and molecules in a liquid-vapour interface.

The availability of powerful tunable X-ray sources is likely greatly to increase our information base and understanding of liquid surfaces. A few of the possibilities we can expect in the next few years are studies of the structure of films supported on liquids and of phase transitions in those films; measurements of the influence of oxidation on the structure of the liquid surface; and investigations of the spatial distribution associated with the excess surface concentration of a component of a mixture. □

Calculating continental strength from thermal history

from Marcia McNutt

SEDIMENTARY basins in continental interiors contain economically important oil, gas and coal deposits. The development of such basins has been largely controlled by the thermal history and mechanical response to sediment loading of the underlying crust and uppermost mantle (the 'continental lithosphere'). N. Kusznir and G. Karner report on page 138 the use of rock deformation data from laboratory experiments to determine directly the mechanical properties of the lithosphere from the thermal history of a basin. In as far as the extrapolation of laboratory experiments to geological loading rates remains valid, their formulation provides a mechanism for inferring the thermal parameters that govern basin development from observations of the mechanical strength of the continental lithosphere through time.

As a first approximation, the long-term mechanical behaviour of the lithosphere resembles that of an elastic plate with strength characterized by its elastic thickness T_e . Rocks above the depth T_e are strong enough to support elastically the stresses imposed by the sediment, whereas rocks below that depth deform ductilely to relax stress. The elastic thickness is primarily controlled by thermally activated creep mechanisms and hence the temperature in the lithosphere. The expectation is that a sedimentary unit deposited on hot, weak continental lithosphere will load a thin elastic plate to produce a narrow, relatively deep stratigraphic horizon. The same volume of sediment deposited on a cold, thick lithospheric plate will produce a broad, thin horizon. Therefore, stratigraphic cross-sections provide information on the mechanical strength, and by inference the thermal state, of the lithosphere during the period of basin formation.

The thermal state of the lithosphere is often summarized in terms of its thermal thickness L , the depth to which conduction as opposed to convection is the primary mechanism of heat transfer, and its thermal age t , which is the time necessary for the lithosphere to cool conductively to its present state from an initial temperature of about 1,300°C (the temperature maintained at its base). A sedimentary basin is thought to form after horizontal tractions stretch and thin the lithosphere (McKenzie, D. *Earth planet. Sci. Lett.* **40**, 25; 1978). Upwelling of hotter mantle isotherms heats the lithosphere. The subsequent cooling and subsidence of the thinned lithosphere are completely described by the initial thermal age t , the

stretching factor β , and the conductive cooling law for a slab of thickness L . Within the context of this thermal description of the continental lithosphere, Kusznir and Karner quantify the expected variations in mechanical strength of basin lithosphere.

The elastic thickness T_e of very old lithosphere (t more than one billion years) is most sensitive to the thickness of the conductive layer L . If L is 125 km — the generally accepted value for the oceanic lithosphere (Parsons, B. E. and Sclater, J. G. *J. geophys. Res.* **82**, 803; 1977) — then the greatest T_e values observed for old continental lithosphere should be about 50 km. Based on observed values of T_e in excess of 90 km for the old lithosphere beneath the Ganges and Appalachian basins, Kusznir and Karner favour a value for L closer to 225 km for continents.

The stretching factor produces observable variations in the elastic thickness by introducing perturbations to the thermal structure. For the expected range in β , extremely stretched lithosphere will seem to have an elastic thickness more than 10 km thinner than modestly stretched lithosphere for sedimentary loads deposited during the first 10 million years of basin subsidence. Decay of the thermal transient gradually eliminates any β -dependence for loads deposited 100 million years later, so that one must study the deepest layers of sedimentary basins to gain insight into the initiating mechanism.

Other factors complicate the simple relationship between elastic plate thickness and thermal anomalies. For example, all rocks below the depth T_e do not relax instantaneously to relieve the stresses from sedimentary loading. Initially, the

deflection of the continental lithosphere corresponds to $T_e = L$, the full thermal thickness of the lithospheric plate. Relaxation begins at the base of the plate, rapidly at first but then asymptotically approaching T_e with time. Thermally young lithosphere ($t = 10$ million years) essentially reaches its long-term value of $T_e \approx 10$ km after only one million years because of rapid cooling of the plate. In older lithosphere ($t = 300$ million years), stresses at the base of the plate continue to relax, so that the effective elastic thickness of about 50 km decreases by a few kilometres between 1 and 10 million years. Therefore, for young loads less than 1 to 10 million years old, transient effects may cause the lithosphere to appear thicker than predicted by the steady-state theory.

The thickness of the crustal portion of the continental lithosphere is another complicating factor. The rocks in the crust, which are rich in quartz, have a lower activation energy for ductile flow than the olivine-rich rocks in the upper mantle. The lower activation energy causes ductile flow in the lower crust at fairly modest temperatures. For a given temperature structure, continental lithosphere seems weaker as the ratio of crustal to mantle portion increases. Thus two different basins both with thermal structures for 100 million-year-old lithosphere can have T_e values that differ by as much as 30 km if their crustal thicknesses differ by a factor of two.

Provided we can make allowance for the nonthermal parameters affecting the mechanical strength of the lithosphere, the elastic flexural signal preserved in sedimentary basins can be used to determine the thermal history which controls hydrocarbon formation. Kusznir and Karner's work identifies the variables and the magnitudes of the effects involved in such thermo-mechanical studies of sedimentary basins. □

Birth defects

Are offspring at risk from their father's exposure to toxins?

from Nigel A. Brown

CONGENITAL malformations can be induced by exposure of the mother to teratogens in early pregnancy, but can they also be caused by treatment of the father before, even long before, conception? The answer, as far as we know it, draws on observations of the effects of genetic lesions, indirectly addressed on page 144 of this issue¹, and on a consideration of potential epigenetic mechanisms.

The various stages of male germ-cell maturation can be differentially susceptible to toxic insult². It is simplest to distinguish two overall phases — pre-meiotic and post-meiotic. The pre-meiotic stem cells produce spermatogonia for the whole reproductive lifespan and they cannot be replaced if destroyed. The lifespans of post-meiotic stages are short by comparison and damaged cells will disappear within one cycle of spermatogenesis, a matter of a few weeks, whereas an abnormal stem cell may be retained for life.

It is possible for treatment of a male to induce genetic damage in germ cells which causes congenital malformation in his offspring. Male mice exposed to X rays or to the mutagen urethane produce fetuses with an increased incidence of malformations^{3,4}. Various common defects are observed, some that would be lethal after birth, others that seem just to be a reduction in fetal size. With post-meiotic exposure of germ cells, up to 4.5 per cent of fetuses are defective, whereas pre-meiotic treatment produces a lower, but still significant, incidence of defects. The malformations are probably caused by both small chromosomal aberrations and gene mutations, and are obviously genetically dominant⁴. Congenital cataracts and skeletal defects have also been observed in offspring sired many months after male mice have been exposed to X rays or ethylnitrosourea⁵⁻⁷. Breeding of these defective offspring has shown (with some technical reservations⁸) that the malformations can be inherited and so are clearly caused by dominant mutations, originally induced in spermatogonia.

Not all embryos produced by mutant spermatozoa result in malformed fetuses. Many embryos die, usually shortly after implantation, due to major aberrations in chromosome numbers or structure induced in post-meiotic stages. Structurally normal offspring can be born with phenotypic changes, ranging from minor coat colour or behavioural abnormalities to potentially lethal biochemical or functional deficits. Limited information suggests that the incidence of cancer in

mice can be increased by paternal treatment with mutagens^{3,9}.

Trasler *et al.*¹ describe birth defects produced by treating male rats with cyclophosphamide, a mutagenic drug widely used in cancer chemotherapy. They confirm that chronic low doses of cyclophosphamide produce many embryonic deaths and report a significant incidence of up to seven per cent malformed fetuses, in contrast to a previous study using a higher dose where only behavioural anomalies in offspring were observed¹⁰. A preliminary report of acute high-dose exposure has also suggested a weak increase in malformations¹¹. The current study uses small groups of treated males, so the number of abnormal fetuses is low and could be due to chance distribution of spontaneous defects, particularly as outbred rats are used. If the malformations are a genuine result of treatment, the observation is significant — many humans are exposed to equivalent doses and there is a suggestion that pre-meiotic germ cells are involved.

Epigenetic mechanisms may also be involved, as some chemicals not usually thought to be genotoxic seem also to affect offspring following paternal treatment. In rodents, paternal exposure to ethanol¹² or narcotics¹³ can lead to reductions in litter size and birthweight, neonatal survival and behavioural deficiencies, but no reproducible increase in malformations. Ethanol may have some genetic effects^{14,15} but it is far from a potent mutagen.

There is little mechanistic evidence to support paternally-induced birth defects by epigenetic events. It seems unlikely that damage to non-genetic components of sperm results in malformations, because recent micromanipulation experiments suggest that sperm cytoplasm is not essential for normal embryogenesis¹⁶. Chemicals can be transported from male to female in seminal fluid or bound to spermatozoa¹⁷ but no fetal malformations have been observed that can be attributed to treatment of gametes at fertilization or of embryos at pre-implantation stages. It seems unlikely that a chemical could retain its activity in the uterus until the embryo reaches the teratogen-sensitive stage of organogenesis.

In humans, epidemiological data suggest that certain occupations increase the risk of fathering an abnormal child¹⁸, but such data are notoriously susceptible to bias from ethnic and socio-economic factors. Two groups of men have been exposed to high levels of genotoxic agents:

survivors of the atom bomb explosions and of cancer therapy. There is no evidence of increased incidence of birth defects in children of people exposed to atomic radiation¹⁹. Men in long-term remission from cancer are less well studied but the current impression is that there is no increased risk of malformation among their children, although this is based on clinical observations with limited power to detect even a modest increase in risk. Because these men represent a unique opportunity to evaluate the possible induction of transmissible genetic damage in humans, efforts should be made to study them carefully.

There has been concern over human exposure to 'Agent Orange' although neither of its components, 2,4-D and 2,4,5-T, or the contaminant dioxin are potent mutagens. No defects have been observed in the offspring of male animals experimentally exposed to dioxin, even though it is an effective teratogen²⁰. Some studies of children of men exposed to Agent Orange have claimed that birth defects are increased but most have not, and none is large or complete enough to be definitive. Several large studies in progress, particularly of Vietnam veterans, should provide more convincing answers²¹.

It would be foolish to advise anything other than extreme caution over the exposure of humans to chemical mutagens when our understanding of the quantitative risks to future generations is so rudimentary. Many fear that the human mutational load is being increased by chemically induced recessive changes which are currently un-noticed. As far as human birth defects are concerned, the limited data are generally comforting but this is not an excuse for complacent inactivity. While we must be thankful that no known chemical induces birth defects by an epigenetic mechanism following paternal exposure, it has to be admitted that such an agent would be an intriguing tool for reproductive toxicologists. □

ANNOUNCING MOLECULAR BRAIN RESEARCH

A section of Brain Research devoted to the publication of molecular studies.

CALL FOR PAPERS

Editor in chief

D.P. Purpura,
Brain Research, Office of the Dean,
Albert Einstein College of Medicine,
1300 Morris Park Avenue, Bronx,
NY, U.S.A.

The powerful techniques and approaches of molecular biology have greatly enriched brain research in recent years. The wide application of recombinant DNA technology, monoclonal antibody production, molecular analysis of receptor-ligand interactions and ion channel mechanisms have generated a wealth of data bearing upon fundamental processes underlying the structure and function of nervous systems. Indeed it is anticipated that reports dealing with the application of molecular biological techniques will increase greatly over the next few years and require appropriate recognition and organization. Cognizant of the need to make such interpretations available to the

readership of **Brain Research**, we are pleased to announce publication of a new section of **Brain Research** entitled '**Molecular Brain Research**.' This decision carries with it awareness of the rapid progress in molecular biology of the nervous system as well as the desirability of encouraging the focus of molecular biological research on brain mechanisms. The Editorial Board of **Molecular Brain Research** will be announced at a later date. Prof. Dominick P. Purpura will serve as Editor-in-Chief of the new section.

Aims and Scope

Molecular Brain Research is a special section of **Brain Research** which provides a medium for the prompt publication of studies of molecular mechanisms of neuronal, synaptic and related processes, that underlie the structure and function of the brain. Emphasis is placed on the molecular biology of fundamental neural operations relevant to the integrative actions of nervous systems.

Subscribers to **Brain Research** automatically receive this section

An essential guide to successful production

This book provides concise and up-to-date information on vegetable crops grown in tropical regions. It contains details of all the factors affecting growth and a clear explanation of techniques that can be applied to increase the level of production. It will be of use to students, extension service staff and research workers who wish to enlarge their knowledge of the range of food crops available for growing in the tropics.

Vegetables in the Tropics provides full information on the cultivation and environmental requirements of about 140 crops.

Hardcover ISBN 0 333 24266 1 £35.00
Paperback ISBN 0 333 24268 8 £15.00

H.D. Tindall is Professor of Tropical Agronomy at the National College of Agricultural Engineering, Silsoe.

GENE EXPRESSION IN BRAIN

edited by **C. Zomzely-Neurath** and **W.A. Walker**, both of *The Queens Medical Center, Honolulu*

This multi-author volume examines the use of biochemical, molecular, biological, and recombinant DNA methodology in resolving problems in neurobiology. It surveys a range of techniques for purifying abundant mRNAs, enriching low abundance mRNAs, and using synthetic oligonucleotides for the

production of complementary DNA for amplification by insertion into plasmids, and cloning and amplification in bacterial vectors.

Modern Concepts in Immunology: A Series of Monographs

0471 862096 312pp June 1985 £49.15

MICROIONTOPHORESIS AND PRESSURE EJECTION

by **T.W. Stone**, *University of London*

There can be few scientists using the techniques of microiontophoresis who have not been dismayed at some time by inexplicably unusable electrodes, variable responses to a given compound, sudden changes of firing rate which ruin an otherwise unblemished recording.

Microiontophoresis is a powerful tool, fascinating and flexible, but the more widespread its use becomes, the more difficult it becomes for people wishing to use the technique to trace those snippets of information, buried in methods, results or even discussion sections of papers, which make the difference between success and failure, jubilation and frustration.

CORRELATIVE NEURORADIOLOGY:

Intracranial Radiographic Analysis with Computed Tomography, Angiography and Magnetic Resonance Imaging, Second Edition

by **R.G. Quisling**, *Department of Radiology, Neuroradiology Section, University of Florida Medical Center* and **P.R. Lotz**, *Department of Radiology, Neuroradiology Section, University of Florida Veteran's Administration Hospital Medical Center*

This book provides the foundations necessary to correctly recognize critical details of brain anatomy, and more importantly, provides a method of correlation among each of the imaging modalities. This edition is a composite of basic neuroanatomy and functional topographic relationships viewed from a radiographic perspective. It concentrates on the strengths of each radiographic imaging method and procedure. Each of the investigative parts contributes data to the final localization of a lesion, the differential diagnosis, and the most likely diagnostic consideration.

0471 89587 3 436pp June 1985 £78.65

STRESS-INDUCED ANALGESIA

edited by **M.D. Tricklebank**, *Merrell-Dow Research Center, Strasburg* and **G. Curzon**, *Institute of Neurology, University of London*

The existence of endogenous pain inhibitory mechanisms is well-established but only recently have systematic attempts been made to understand the physiological circumstances under which these mechanisms are activated. Stress seems to play a key role in such activation and this book attempts to define and explore further the neurochemical and physiological effects of stress on nociception.

0471 90430 9 204pp September 1984 £19.50

MOLECULAR BASES OF NEURAL DEVELOPMENT

edited by **G.M. Edelman**, **W.E. Gall** and **W.M. Cowan**

Emphasizing cellular interactions at the molecular level, this volume presents work on the embryological development of the nervous system. It contains sections on primary processes in early development, on the role of glia and cell migration in the central nervous system and in the periphery, of the formation of neurites and synapses, development of the retinotectal map, and molecular genetic approaches to analysis of neural development. Included are examples from both vertebrate and invertebrate development, and the experimental results on the complex pattern of temporal and spatial interactions that give rise to the adult nervous system.

Series: The Neurosciences Institute Publications

THE PSYCHOPHARMACOLOGY OF EPILEPSY

edited by **M.R. Trimble**, *The National Hospital for Nervous Diseases, London*, and *the Institute of Neurology, University of London*

As part of their treatment, epileptic patients with associated psychopathology often receive psychotropic drugs in addition to anticonvulsant medication, but there is scant information available to clinicians on how these two drug groups interact. This book therefore presents a review of some of the latest research in this area, and then develops its theme to include an examination of kindling as a possible model for the development of behaviour disturbances in epileptic patients.

0471 90672 7 196pp May 1985 £21.50

DIAGNOSIS AND PSYCHOPHARMACOLOGY OF CHILDHOOD AND ADOLESCENT DISORDERS, Second Edition

edited by **J.M. Wiener**, *George Washington University School of Medicine*

Clinicians research and scientists survey the current principles and practices of using psychoactive medication to treat childhood psychiatric disorders. Organized by DSM-III diagnostic categories, the second edition explores the clinical conditions that can be treated effectively by medication such as stimulants, antipsychotics, and antidepressants. In addition, it provides a review of the most up-to-date literature in the field and surveys the adverse effects of psychoactive drugs.

David Dickson

Lost at the Frontier: US Science and Technology Policy Adrift.

By Deborah Shapley and Rustum Roy.

ISI Press: 1985. Pp.223. Hbk \$19.95, pbk \$13.95.

THE way Western countries — and Eastern ones too, for that matter — choose to organize their science usually reflects more general attitudes about the role of the state in the economy. In Britain, for example, central planning of both spheres has always been weak, and the research system is permitted considerable autonomy, provided it observes various loosely-defined social conventions. France, in contrast, applies much stronger centralized control to its science, in line with administrative traditions that stretch back past Napoleon to Louis XIV and his adviser Colbert; while in countries such as Italy, where the state apparatus, though large and cumbersome, has less real power, the organization of science is more pragmatic and reflects initiatives taken by influential individuals.

The United States is no exception to this pattern. Largely as a result of the Congressional system, the structure of federal support for science — like that for the broader economy — results as much from efforts to balance pressures from a mosaic of frequently-conflicting lobby groups as it does from any carefully-crafted philosophy or government strategy. The evolution of scientific institutions in the United States provides a concrete testimony to the effectiveness of these pressures, whether in the form of a new research institute added to the National Institutes of Health at the prompting of a group of medical charities, or a space station eagerly promoted by sectors of the aerospace industry.

One result is that it is virtually impossible to identify a single, clear science and technology policy in the United States. Is this the most sensible way of running a research budget that is larger than the economic turnover of some European countries? Deborah Shapley, previously Washington correspondent for *Nature*, and Rustum Roy, head of the materials science laboratory at Pennsylvania State University, say no. The argument sketched out in their book *Lost at the Frontier* is that, whatever its undoubted strengths, the American research system is not contributing as much as it could be to the country's well-being, largely because it is insufficiently co-ordinated.

The book starts from the thesis that the bold plans put forward by Vannevar Bush in the years immediately following the Second World War for the renovation of American science have been betrayed by a lack of imagination and leadership. Bush

argued for increased and continuous government support for basic science — “the endless frontier”, to quote the title of his famous 1945 report — primarily as a means of achieving economic prosperity; yet this objective rapidly gave way, argue Shapley and Roy, to the philosophy that basic science was a desirable end in itself.

This “basic-research-is-best” ideology, they say, still dominates the thinking of both the scientific community and the Reagan administration. Not only has it contributed to a downgrading of research explicitly aimed at practical goals, but it has also led research workers to consider that they have a right to continued and generous support from government, regardless of whether their results are of use or value to anyone else. And this in turn has driven a wedge between the world of science and that of its technological applications which can be blamed for many of the problems currently faced by the American economy.

Even if much of what Shapley and Roy have to say about such problems has been heard many times before, their criticisms are worth repeating. It is still too easy for scientists to hide behind the argument that, since their sole motivation is intellectual, they are under no obligation either to discuss the social implications of what they are doing, or indeed to concern themselves in any way with its potential technological applications. It is also true that there are some areas of research where a greater consistency in federal support would have been more productive. One of the book's most revealing case studies concerns Roy's own field of ceramics, where wild fluctuations in government enthusiasm — and thus funding — have clearly been harmful when compared with the sustained interest that the field has received in other countries, particularly Japan.

Three central questions, however, are raised by the general thrust of Shapley and Roy's argument. Is it true that American research policy remains dominated by a “basic-research-is-best” attitude which undermines efforts to link science and technology? Would the situation be improved by a central, guiding authority? And could such an authority operate effectively within the existing institutional structure of American politics?

In each case, there is firm evidence to contradict the claims made by Shapley and Roy. On the first, for example, it is certainly true that, through a process

which started during the Carter administration and has accelerated under President Reagan, the main emphasis in government funding for science has swung back from “applied” research programmes in fields such as energy and transport towards more “basic” projects. Yet as government spokesmen frequently emphasize, this shift has taken place not for abstract, cultural reasons, but because of the twin beliefs, now widely shared in top government and industrial circles, that basic research represents a long-term investment in the technology of the future, and that the market-place — rather than a political planning committee — is the appropriate mechanism by which this investment should be realized.

Secondly, attempts to impose directions on science from the centre can be stifling rather than stimulating, however enlightened the policy-makers. Shapley and Roy describe at some length the successful efforts of Japan; but they make no mention of France, where the experience of central planning for science has been much less fruitful. Nor do they look closely at the highly decentralized (and basic-research-orientated) structure of the biomedical research community in the United States, whose vitality, when combined with the vigour and enthusiasm of the venture capital market, has been the key factor in determining America's dominant position in the global biotechnology industry.

Finally, their proposals are put forward in a political vacuum, assuming that rational discussion will lead to consensus between experts from industries, universities and government on appropriate national research priorities. In practice such priorities (ranging from synthetic fuels to the Strategic Defense Initiative) are frequently determined by non-technical arguments. The fact may drive some scientists to despair; but it needs to be seriously considered by anyone who proposes radical changes in the current pattern of decision-making. For example, in discussing the increasing restrictions placed on scientists attending conferences on topics that could have military implications, the authors describe this as merely the result of misguided political interference in the practice of science. They do not analyse in any detail the various factors that have given rise to these conflicts, such as the increasing amount of “basic” research that has a clear and direct relevance to both civilian and military technology almost simultaneously.

Shapley and Roy make several interesting suggestions about how the organization of American science could be improved. These range from various proposals for streamlining the peer review system (for example, by increasing the number of multi-annual grants and placing greater weight on prior performance), or imposing a greater concentration of government

funds on centres of research excellence, to allowing scientists to spend part of their working time doing voluntary teaching in schools (a practice recently adopted in France). Other suggestions are included in a series of responses to their case solicited from various prominent figures such as President Eisenhower's science adviser, James R. Killian, and Edwin H. Land of Polaroid camera fame. (Unfortunately most of these luminaries use the opportunity to present their own views on how science should or should not be run, rather than give detailed opinions on the ideas of the two principal authors.)

In the end, however, any arguments about the optimal strategy for science and technology which emphasize questions of internal structure, such as the relative weighting to be given to basic, "strategic" and applied research, without paying equal attention to the political logic of the external pressures which frequently determine this internal structure, inevitably appear idealistic, if not utopian. To argue, like Shapley and Roy, that American science is "lost at the frontier" and that science policy is "adrift", implies that a map and a rudder would answer the basic problems. But this raises the all-important question of how (or whether) agreement will be secured on a single map — or whose hand will be allowed on the rudder. And it can be argued that one of the most important changes in American science policy over the past decade has been the increasing influence that private industry and the military have been able to exert over precisely these processes.

There has been a long tradition of members of the scientific community declaring a strong aversion to the untidiness of the procedures by which rudimentary political issues, including the control of the direction of science and technology, tend to be resolved in society. If only, it is often argued, the organization of science — and of society too — could be made more scientific, conflicts and inefficiencies would be eliminated and the whole enterprise would immediately become more productive.

Shapley and Roy clearly share such hopes. Their optimism is to be admired, and there are sectors of the research enterprise in the United States where their solutions are certainly appropriate. But their insistence on the supremacy of scientific management risks overlooking the extent to which the cracks currently appearing in the American research system can be read as symptoms — rather than causes — of broader economic and political conflicts. It also underestimates how far these latter factors need to be taken into account if a truly rational policy for science and technology is to be achieved. □

Truths of planetary evolution

S.R. Taylor

The Geology of the Terrestrial Planets. By Michael H. Carr, R. S. Saunders, R. G. Strom and D. E. Wilhelms. *NASA: 1984. Pp. 317. \$16 (North America), \$20 (elsewhere).*

EVERY geologist should be familiar with the landscapes and geological processes of the Moon and nearby planets, if not on account of their inherent interest then because of the insight and perspective which they shed on terrestrial geology. The authors of this volume have all made signal contributions to planetary geology, clearing away in the process much of the pre-Apollo confusion, and here provide an up-to-date and readable summary of our present understanding of the subject. Those scientists who dismiss geological evidence as merely pictorial in nature would do well to read this book and perhaps discover that hard truths about planetary evolution do emerge from the study of landscapes. Even students of cosmology should be interested to learn that the radius of Mercury shrank by a kilometre or so about 4×10^9 yr ago but, like the Moon, has remained static since that time, placing limitations on the variation of G and causing disarray among proponents of expanding Earth hypotheses.

Many questions remain to be answered. Are the smooth plains of Mercury really analogous to lunar maria or are they ejecta blankets? The composition of Mercury is clearly distinct from that of the Moon, and the recent failure to confirm, by reflectance spectra, the presence of Fe^{2+} on the surface must arouse doubts about their volcanic nature. A further problem is whether heavily cratered surfaces, on Mercury and in the lunar highlands especially, are saturated with craters, or constitute a production population. In the latter case, we can read the history of the surface since accretion. The former possibility, that we see only the record of the closing stages of the great meteoritic bombardment, implies that the observed lunar highland surface is no older than 4.1 or 4.2×10^9 yr. This seems more likely to me. Equally contentious is the existence of the giant Procellarum basin, 3,200 km in diameter, which may underlie much of the visible face of the Moon. Wilhelms's overview of lunar multi-ring basin stratigraphy removes the basis for the once popular "lunar cataclysm" hypothesis. The nature of the Tharsis bulge on Mars, whether a plateau uplifted by internal forces, or constructed by volcanic flows, remains open, but evidence for the former presence of flowing water on Mars seems unequivocal. The surface of Venus is perhaps analogous to

earliest Archaean times on the Earth. Evidence of granitic or other siliceous rocks, so typical of the continental crust of the Earth, appears to be minimal for Venus and the other planets; such rock types, familiar even to city dwellers as facings of buildings, may thus be uniquely terrestrial, a consequence of the abundance of liquid water.

The geological study of the terrestrial planets continues to flourish. More recent discoveries of many multi-ring basins on Mercury and the possibility that the lunar megaregolith is 25 km deep do not appear in the book, but it is nonetheless commendably up to date. Overall editorial control appears to have been satisfactorily light, so that the expertise and style of the individual authors (Strom on Mercury, Saunders and Carr on Venus, Carr on the Earth and Mars, and Wilhelms on the Moon) show through clearly.

Minor failings include an inadequate index of three pages (partly offset by a four-page table of contents). References are given at the end of the book, by chapter, but a combined reference list would have been preferable. Don Wilhelms will be especially chagrined to find that his beautiful plates (C and D on pp. 202–205) of the palaeogeography of the Moon have been transposed. And the maps, 18 pages of them at the end of the book, are really too small; NASA, unconstrained by the limitations of commercial publishers, would have been better advised to have included their useful larger series of planetary maps in a pocket.

This is a valuable contribution to the literature dealing with the terrestrial planets. It provides an excellent basis for university courses in the geology of the terrestrial planets as well as solid reading for geologists involved in the subject. □

Chemical reference in English

Two of the oldest and best known reference works for chemists, *Beilstein Handbook of Organic Chemistry* and *Ullmann's Encyclopedia of Industrial Chemistry*, published in German for 104 years and 71 years, respectively, are now appearing in English.

Beilstein consists of a main series and five supplementary series. Publication in English has started with Vols 17–27 (heterocycles) of the fifth supplementary series (EV) of the fourth edition, covering the literature from 1960 to 1979. Executive editor of the work as a whole is R. Luckenbach of the Beilstein Institut, publisher is Springer-Verlag.

Ullmann's in English is to be a 36-volume series — 28 "A" volumes (alphabetically arranged articles) and 8 "B" volumes (basic knowledge), to appear at the rate of three or four a year — and commenced with Vol. A1 of the fifth edition, *Abrasives to Aluminum Oxide*. Executive editor is W. Gerhartz and publisher is VCH.

It came from space

Peter Kemp

Comet Halley: A Novel. By Fred Hoyle. Michael Joseph: 1985. Pp. 410. £9.95. To be published in the United States later this year by St Martin's Press.

WHAT'S most astronomical about Fred Hoyle's new novel, *Comet Halley*, is the number of different subjects packed into its pages. The book sets out to be a love-story and a political satire, a thriller, a spy mystery, an exercise in science fiction, a pacifist tract, a comedy of Cambridge manners and an essay in evolutionary theory. Like the heavenly body at the heart of its narrative, it whizzes along — sometimes garish, sometimes gaseous — throwing off material in all directions.

The story opens with scientists in Cambridge, England, amazingly receiving radio messages beamed from Comet Halley. As excitement about this mounts, so does the local death-rate. Researchers expire in unusual circumstances; there are murders, lethal booby-traps, a deadly bombing; several characters are found mysteriously charred to death. Gradually sorting out what's behind all this is the improbably-named Isaac Newton: no relation to the seventeenth-century luminary but like him in opening up a new dimension in thinking. For, along with Frances Margaret, a brainy beauty who becomes his lover, he reaches the conclusion that Comet Halley harbours life — and life of a civilized and civilizing disposition. Comprising "a biologically generated nuclear reactor", it seems, the comet is directing itself to the prevention of nuclear war on Earth.

Soon, in his efforts to assist the comet in its pacific purposes, Newton is striding down the corridors of power (echoes of C. P. Snow keep reverberating through this ambitious sprawl of a novel), trying to convince politicians that humanity is on the brink of a momentous breakthrough. If only nations would realize the folly of pouring money into military budgets and divert resources into the building of telescopes instead, it's argued, then they will be able to receive and re-direct messages from Halley and a host of other would-be communicative comets throughout the Galaxy. The Earth, Newton points out, could become the hub of "a sort of cosmic telephone exchange", "an extra-terrestrial communications system". Since each comet is "a giant brain by our standards", the linking of them all into one vast network of brainwaves must result in hitherto undreamed-of intellectual advances.

Factors standing in the way of this — scepticism, militaristic bigotry, the stockpiling of nuclear weapons — are robustly guyed and decried in this book. Likewise, those who attempt to deflect Comet

Halley's benign aims find themselves having a hard time. When not actually reduced to blackened stalagmites by long-distance emissions from the peace-loving projectile, they succumb to curious maladies: in Moscow, the Politburo go down with "the mad itch", an extra-terrestrial ailment that plagues people into frenzies of nude scratching; the population of Washington is afflicted by a strange derangement which brings on an irresistible urge to hibernate. Finally, ramming its aims home with some emphasis, the comet bombards the Arctic with a guided missile, pulverizing the ice-cap and hastening a change in the climate of opinion on Earth by drastically altering the planet's weather.

As if this weren't striking enough, Hoyle throws in further excitements for good measure: there's a particularly grisly sub-plot involving "a flying torture chamber" staffed by a quartet of odd-shaped psychopaths: a sadist with a Neanderthal skull and larger teeth than is customary, an ape-like giant, a vicious dwarf and a "ghastly waxen-faced creature" with shoulder-length white hair who wields a syringe filled with some unbearably agonizing concoction. Injecting one dramatic incident after another into his plot, Hoyle is generous to

a fault with dramatic incident — but always for didactic purposes. In as eye-catching a way as possible, *Comet Halley* is designed to trail its author's views on the emergence of life — and the likely extinction of it on Earth unless there's a change in thinking. □

Grains of evidence

Peter D. Moore

The Palynology of Archaeological Sites. By Geoffrey W. Dimbleby. Academic: 1985. Pp. 176. \$45, £34.50.

POLLEN analysis has proved a valuable asset in the investigation of archaeological sites, though the problems involved in its application have not always been adequately appreciated. Only rarely are such sites conveniently located close to deep lake or peat sediments which permit extensive environmental reconstruction; more often the archaeologist has to make do with a buried soil, an infilled ditch or a compacted cave deposit. And such unconventional sources require specialized techniques of sampling and interpretation.

Geoffrey Dimbleby has been the pioneer in this field and has now brought together the collated wisdom of his years of research. It is a book with a strong practical emphasis, reflecting the fact that Dimbleby has been concerned not only with the laboratory analysis of samples but also with the collection of materials in the field. Such field experience shows through in the discussion of the various sources of polleniferous material and in the helpful warnings given about the limitations

that are imposed by different site factors.

Very naturally, much of the book is given over to soil pollen, Dimbleby's principal interest. This subject, which has been neglected and undervalued by most palynologists, has long required the kind of detailed and frank scrutiny which Dimbleby has here provided. He examines the many processes, such as the downwash and the faunal mixing of pollen, which prevent the simple interpretation of soil pollen profiles as stratified sequences.

As well as dealing with interpretive problems, the book contains many of Dimbleby's soil pollen diagrams which illustrate the kind of information to be gleaned from soil pollen profiles. Perhaps this aspect should have had less prominence, however, since these diagrams are readily available elsewhere and undoubtedly contributed to the book's high cost.

The author's cautious attitude to the application of pollen analysis and interpretation of the results may dismay some archaeologists who expect rather too much from the technique. But the book should be welcomed as a timely damper on those exuberant spirits whose enthusiasm outpaces their data. □

Going through the changes

Mark Johnson

On the Nature of Human Plasticity. By Richard M. Lerner. Cambridge University Press: 1984. Pp.208. £17.50, \$29.95.

"PLASTICITY" is one of those labels that has taken on a variety of different, but overlapping, meanings. For example, the neurophysiologist may use the term to refer to the capacity of the nervous system to regenerate or reorganize after injury or environmental change, while some psychologists choose to reserve the term for the possible range of variation that can occur in individual development. Because of this confusion of meanings, it is essential that anyone setting out to integrate information on "plasticity" from various disciplines (in this case genetics, neurobiology, evolution, individual and group psychology) should adopt a clear and precise definition. In his book, however, Richard Lerner appears to be content to allow his interpretation of the word to emerge from the interaction between the reader and the 174 pages of text. This is both a strength and a weakness. While it enables the author to apply the term to everything from molecular genetics to social relationships, the price to be paid is the rather doubtful usefulness of his conception within some levels of explanation.

Two main theses with regard to human development are put forward in the book. First, Lerner suggests that "plasticity" is not confined to the early years but exists throughout the entire life-span. The "life-span" developmental view is a recent school of thought in psychology which emphasizes the capacity for change in the adult. This emphasis on the adult allows its proponents, including Lerner, to use "plasticity" to refer to any changes in structure or function in the organism. However, when this conception of the term is confused with "plasticity" as a specific response to the environment, which it is in the book, the reader is left with the implication that all developmental change is environmentally specified. And this while claiming to have moved beyond the old nature-nurture debate.

The second main thesis is that variables and processes at different levels (biological, individual psychological, dyadic, social and so on) may contribute to human functioning at any one time. These levels do not work independently, in parallel, but are reciprocally influential. Each level is seen to be "embedded" within the others. Lerner formalizes this idea in a framework for describing the development of individuals within their multi-levelled environment. However, as he himself admits, this framework merely constitutes a specification of the domain

within which future theory and research about individual development should be generated. Its usefulness can only be assessed by the success or otherwise of the models it gives rise to. Even if successful at the psychological level, it is not clear whether such a framework would be appropriate at, for example, the neurobiological level. Equivalence of terminology does not imply equivalence of mechanism.

Lerner sees the ideas presented in the book as being of consequence for the clinician. Since each "level" is engaged in dynamic interaction with the others in which it is embedded, it follows that intervention by the clinician at one level will have effects at other levels. For example, changing an individual's diet may have an influence on neurotransmitters which may then have effects on behaviour, and

thence on dyadic and other social relationships. The effects at other levels may be beneficial or detrimental, but in order to predict them some understanding of the mechanisms of interaction between levels is required. Lerner offers us only description, and description is not adequate for prediction.

In his foreword, Paul Baltes states that despite his approval of the book he is convinced that the author will be criticized for his commitment to interdisciplinary breadth. On the contrary, such a commitment is to be applauded. However, the synthesis we are offered in this book is, like all mirages, attractive at a distance but elusive close up. □

Nonsenses of today

Joseph Silk

Perfect Symmetry: The Search for the Beginning of Time. By Heinz R. Pagels. Simon & Schuster. 1985. Pp. 329. \$18.95. To be published in Britain later this year by Michael Joseph.

PARTICLE physics and cosmology have developed a symbiotic relationship. While it would take a particle accelerator stretching from here to Alpha Centauri to smash particles together at energies approaching the grand unification scale (and we may safely consider this to be outside the future budgets of CERN or Fermilab), such energies were reached routinely in the very early Universe. Hence the attention being paid by particle theorists to constraints from cosmology. Already, many exotic theories have been eliminated, and others, phoenix-like, have arisen. Does the dark matter that pervades the visible Universe consist of massive chunks of quark matter at nuclear density? Or does it consist of shadow matter, a whole universe of stars and galaxies, invisible to us apart from their gravitational interaction?

This book by Heinz Pagels, a particle physicist, provides a lucid introduction to the interplay between cosmology and particle physics. He describes the motivation and basis for grand unification theories, and their role in cosmology, and includes a chapter on the inflation of the Universe, one of the most notable results of the synthesis between particle physics and cosmology. Inflationary cosmology provides a scientific basis for understanding why the Universe is so large, and why it is so isotropic (that is, similar in all directions). It explains why the Universe is almost, but not quite, uniform: from the primordial fluctuations in density, the galaxies eventually grew.

Although the hottest topics from last year's conference season, such as quark nuggets or shadow matter, are inevitably absent, there is a sufficiently solid introduction to the new physics that the reader will have little difficulty in making sense of the latest developments that appear in the semi-popular press. But to give him full credit, Pagels does not hesitate to tackle some vertiginous issues. What happened before the big bang? What was the origin of everything? Our Universe may well have begun as a quantum fluctuation: before, there was nothing, not even time or space, but absolutely nothing.

Much of the text is devoted to an account of the astronomer's Universe. The latest discoveries from space astronomy are described, ranging from the infrared-emitting embryo stars being hatched deep within dense interstellar gas clouds to the tenuous hot plasma glowing in X-rays throughout megaparsecs of intergalactic space in the great galaxy clusters. All of this, and a capsule description of the evolution of the big bang, from the beginning of the knowable Universe, some 10^{-43} s after the initial singularity, until about 1×10^{10} yr later.

The book is written for the intelligent layman, and thus non-technical and not unduly laden with jargon. It is, however, replete with quotations that help communicate the excitement at the frontier of science. My favourite is Eddington's reaction to the discovery of the first white dwarf star, Sirius B, supposedly made of material thousands of times denser than any known matter: "Shut up. Don't talk nonsense". Eddington's comment has been repeated many times since in reaction to novel observations or experimental data: seventy years later, it remains to be seen whether we have truly learned our lesson. □

Lorentz resonances and the structure of the jovian ring

Joseph A. Burns*, Leslie E. Schaffer*, Richard J. Greenberg† & Mark R. Showalter*

* Cornell University, Ithaca, New York 14853, USA

† Planetary Science Institute, Tucson, Arizona 85719, USA

Charged dust orbiting through spatially periodic planetary magnetic fields will experience time-variable electromagnetic forces. When the forcing frequencies are nearly commensurate with the particle's orbital frequency, the particle undergoes large out-of-plane and radial excursions. Specific 'Lorentz' resonances, corresponding to particular spatial periodicities in the magnetic field, occur on either side of synchronous orbit. We describe here Lorentz resonance locations and strengths for the jovian and saturnian rings. The boundaries of the halo of the jovian ring, and perhaps other ring structure, are near resonances.

ORBITAL resonances, those positions at which periodicities in perturbations are commensurate with the orbital period of a test particle, have long been suspected to govern much of the structure of the Solar System. For example, gaps and concentrations are found in the asteroid belt at positions where the orbital period of a particle would be close to a simple fraction of Jupiter's orbital period^{1,2}. Similarly, the Voyager spacecraft discovered some 50 cases of ring edges, isolated narrow ringlets, gaps or wave trains in Saturn's rings located at resonances with nearby satellites^{3,4}. On the other hand, it is unlikely that the uranian rings reside at three-body resonances (as once suspected⁵) because the putative resonances are too weak^{6,7}. As well as the above resonances, which are produced by the periodic pulls of orbiting perturbers, 'lumpiness' in a planetary gravitational field could affect particles having orbital periods that are fractions of the planet's spin period⁸ (compare with ref. 9); but recent refinements in ring dimensions show no unusual features at such locations³.

Only in the case of Jupiter's ring¹⁰ have resonances not been invoked extensively (see ref. 11), perhaps because satellite perturbations are weak since neighbouring moons are either distant or small, and because collective gravitational effects are thought to be non-existent in such a tenuous structure¹⁰. We show here that several features of the jovian rings are, however, near 'Lorentz' resonances and we outline how this connection might be enforced^{10,12}. We also point out that the ring's outer edge is close to a feeble satellite resonance; if this association is confirmed by the Galileo spacecraft, the workings of resonances may have to be reappraised.

Lorentz resonances

Electromagnetic forces have been shown to be significant for jovian ring particles, especially as the possible cause for out-of-plane motion^{10,12-15}. Accelerations $[(q/mc)\mathbf{v} \times \mathbf{B}]$ resulting from Lorentz forces are fairly strong perturbations because: (1) jovian particles have large velocities $\mathbf{v}$ across an intense magnetic field $\mathbf{B}$; and (2) their electric charge-to-mass ratios q/m are generally larger than for members of other ring systems because most visible jovian grains are tiny (of the order of a micrometre^{10,12}) and adopt an electric potential V determined by the surrounding magnetospheric plasma and estimated at -10 V (refs 10, 16, 17). The jovian magnetic field is far from an aligned dipole^{18,19}; in a multipole representation, the quadrupole and octupole terms contain 30% of the strength¹⁸. Accordingly, the Lorentz force on a jovian ring particle varies substantially even for a particle of fixed charge travelling along an equatorial circular orbit. Specifically, a particle in a pure dipole field would experience varying radial forces if the dipole were tilted or were offset equatorially; a constant latitudinal force would be produced by an axially offset field and a variable one by a tilted field.

A particle orbiting a planet with a spatially periodic magnetic field will experience a temporally-variable electromagnetic force

as it passes through the various frequency components of the field. Lorentz resonances are said to occur at those positions where orbital periodicities match a periodic component of the Lorentz force, for then the perturbing force will be in phase with the particle's natural oscillatory motion. This elementary viewpoint has been supported by a perturbation solution¹⁵, where the equations of motion are found to be those of forced, linear harmonic oscillators. To locate Lorentz resonances, we assume that in the neighbourhood of the ring the jovian magnetic field $\mathbf{B}$ can be derived from a potential function ψ (refs 18, 19) due either to current sources in the planet or at great distances from it. ψ can be represented by an infinite series of spherical harmonic functions, such that for internal sources

$$\mathbf{B} = -R\nabla \sum_{l=1}^{\infty} (R/r)^{l+1} \sum_{k=0}^l P_l^k(\cos \theta) [g_l^k \cos k\phi + h_l^k \sin k\phi] \quad (1)$$

where R is the planet's equatorial radius, (r, θ, ϕ) are the usual spherical polar coordinates measured relative to the rotating planet, $P_l^k(\cos \theta)$ are the Schmidt-normalized associated Legendre functions, and g_l^k, h_l^k are the observationally-determined Schmidt coefficients defining the field.

As each component of the field is a trigonometrical function of the longitude ϕ , an equatorial particle moving with a mean orbital angular velocity n would experience the k th spatial component of the field to vary with a frequency $k(n - \Omega)$, where Ω is the spin rate of the magnetic field (planet). Lorentz resonances are present at those radial positions where this frequency matches local epicyclic frequencies, defined as the rates κ and μ at which a test particle displaced by an arbitrary small amount will oscillate about the reference circular orbit in the horizontal or vertical directions²⁰. Ignoring planetary oblateness for the moment, the horizontal (κ) and vertical (μ) epicyclic rates equal n . Hence the resonance condition is approximately

$$k(n_k - \Omega) = n_k \quad (2)$$

where n_k is the mean motion of a particle at the k th resonance; a positive k is appropriate if $n_k > \Omega$ (that is, resonances interior to synchronous orbit defined as the radius R_{syn} where $n = \Omega$), whereas a negative k corresponds to exterior resonances. Morfill and Grün²¹ have found independently a similar resonance in connection with the motion of charged dust across the sector structure of the interplanetary magnetic field.

Figure 1 illustrates the operation of a typical Lorentz resonance pair. The radial portion of the $k=2$ magnetic field component is outward in two quadrants and inward for the remaining two, if we define zero longitude such that $g_2^1 \equiv 0$ in equation (1); although the strength of the $k=2$ component varies sinusoidally across a quadrant, that is unimportant for this heuristic description. Negatively charged particles at the interior and exterior resonant orbits each experience out-of-plane Lorentz forces. The force on the interior particle at the location

Fig. 1 Two equatorial particles—one at the interior $k=+2$ Lorentz resonance and another at the exterior $k=-2$ resonance—in four views from the North Pole. The outward and inward arrows represent the radial part of the planet's magnetic field that has $k=2$ periodicity; the planet, drawn as a solid circle, rotates by $\pi/2$ (relative to inertial space) in each successive panel. For each of the two orbits the Lorentz forces ($\bullet$, out of the plane of the paper and $\oplus$, into the plane of the paper) change sign every π radians of inertial space; these forces thereby induce north-south motions, that is, they produce inclined orbits. Large radial excursions of the orbit will be similarly generated because the latitudinal field also contains a $k=2$ periodicity. The synchronous orbit ($\Omega=n$) is shown dotted in *a*.

shown in Fig. 1*a* is out of the plane of the paper (as v , the velocity relative to the field, is positive) but the force on the exterior particle at the same longitude is into the plane of the paper (as relative v is then negative).

In Fig. 1*b*, the magnetic field has rotated by $\pi/2$, and the interior particle (having orbited through π relative to inertial space) now feels a southward force. The other particle, having travelled only $\pi/3$ radians, still remains in the first quadrant with its outward-pointing field, and so its force remains southward, although smaller than initially.

After another quarter rotation of the planet (Fig. 1*c*), the inner particle is back to its starting point (but now above the opposite face of the planet). The force on the particle at the $k=-2$ resonance has finally reversed, so both are subject to southward forces.

In Fig. 1*d*, the two particles are aligned once again, exactly π from their configuration in Fig. 1*a*, and both experience forces with opposite sign from one another and from those in Fig. 1*a*. The cycle now repeats itself. During its 3π longitudinal excursion, the interior particle has been pushed up and down twice, whereas the particle at the exterior resonance has only travelled π radians and gone through half a force cycle. Each has been pushed up on one side of its orbit and down on the opposite side exactly in phase with the orbital motion.

In terms of equation (2), the interior resonance of Fig. 1 is found at that radius where the mean motion satisfied $2(n_{+2}-\Omega)=n_{+2}$, or $n_{+2}=2\Omega$, whereas the exterior resonance is defined by $-2(n_{-2}-\Omega)=n_{-2}$, or $n_{-2}=(2/3)\Omega$; as already shown in Fig. 1, $n_{+2}/n_{-2}=3$. Clearly, the $k=+1$ (interior) resonances can never be achieved because the perturbation frequency observed by the particle $(n-\Omega)$ is everywhere $<n$. Furthermore, resonances become more and more closely spaced (but generally also

weaker as we will show) when the synchronous orbit position is approached from either side.

Using Kepler's third law to express n in terms of r , the k th resonance is approximately located at

$$r_k = \left[\frac{k-1}{k} \right]^{2/3} R_{\text{syn}} \quad (3)$$

The interior k th resonance is found by substituting positive integers while the exterior k th resonance is located with negative integers.

R_{syn} can be calculated to be at $2.2444R_J$ for Jupiter, while for Saturn $R_{\text{syn}}=1.8651R_S$, if the effects of the higher-order gravitational moments J_2 and J_4 are included.

To locate the resonances more precisely, the expressions for the epicyclic frequencies κ and μ should include higher-order gravitational moments, which cause $\kappa < n < \mu$ and, therefore, mean that the vertical and horizontal resonance positions split. Substituting classical expressions²² for n , μ and κ , accurate to J_2 , into equation (2) with the right-hand side replaced by μ , the k th vertical Lorentz resonances are at

$$r_{kv} = [(1-k^{-1}) + (3/4)(1-3k^{-1})J_2(R/r_k)^2]^{2/3} \times R_{\text{syn}}/[1 + (3/4)J_2(R/R_{\text{syn}})^2]^{2/3} \quad (4)$$

Horizontal Lorentz resonances are found by replacing n on the right-hand side of equation (2) by κ to yield

$$r_{kh} = [(1-k^{-1}) + (3/4)(1+k^{-1})J_2(R/r_k)^2]^{2/3} \times R_{\text{syn}}/[1 + (3/4)J_2(R/R_{\text{syn}})^2]^{2/3} \quad (5)$$

(Note that the signs of the second and fourth terms for κ are wrong in ref. 22.) Expressions (4) and (5) are equally valid for

interior and exterior resonances as long as k is taken to have a positive and negative sign, respectively. As $J_2 \ll 0(10^{-2})$ for all planets, these expressions can be solved rapidly by successive approximation. More exact expressions for n , κ and μ involve J_4 and J_2 (ref. 2), which introduce corrections of $0(10^{-4}-10^{-5})$ to equations (4) and (5). These terms have not been included because comparable or larger corrections will arise by direct electromagnetic effects: n itself will depend on the particle's charge-to-mass ratio because centrifugal balance should include the constant radial component of the Lorentz force, which generally will shift resonances by small amounts that depend on k .

To a lesser extent, the exact positions of the resonances are uncertain because the various harmonics of the magnetic field might rotate at slightly different rates (D. J. Stevenson, personal communication); for example, the non-dipole part of the Earth's field drifts westward relative to the surface at $\Delta\Omega/\Omega \sim 10^{-5}$, and, accordingly, resonant positions would be translocated by a comparable fraction.

We estimate the relative strength of the k th Lorentz resonance from the latitudinal force that has k periodicity. This is proportional to $v_{\phi k} B_{\phi k}$, where $v_{\phi k} \equiv r_k(n_k - \Omega)$ is the longitudinal speed of the particle across the part of the radial magnetic field B_r that has k periodicity. We estimate $B_{\phi k}$ by the term in equation (1) that has k periodicity and the lowest power of R/r_k . The coefficient of this term is $(|k|+1)(R/r)^{|k|+2} P_k^k(0) C_k$, where C_k is defined as $[(g_k^2) + (h_k^2)]^{1/2}$ and serves as a measure of the relative importance of the k th component of the field. Hence the strength S_k of the k th resonance is proportional to

$$S_k \sim \frac{(|k|+1)}{(1-k)} \Omega R (R/r)^{|k|+1} P_k^k(0) C_k \quad (6)$$

This expression pertains to latitudinal forces; the radial forces are comparable.

The resonances that we have just described are appropriate for the linearized problem. A more complete treatment would incorporate nonlinear terms, including a coupling between the radial and latitudinal motions. Based on the classical theory of coupled, forced nonlinear oscillators, we anticipate that the solution to the full nonlinear problem will contain features not present in the strictly linearized equations. The locations of the higher-order (nonlinear) horizontal Lorentz resonances can be found by generalizing equation (2):

$$k(n_k - \Omega) = K n_k \quad (7)$$

where K is a small integer; for vertical Lorentz resonances, the right-hand side of equation (7) would also be $K n_k$ with the appropriate higher-order corrections included in n_k . Because of non-linearity, super- and sub-harmonic resonance motions might be achieved at such positions. New locations are introduced through equation (7) and the previous positions of equation (4) can be shifted slightly because the 4:2 resonance does not lie on top of the 2:1 resonance since higher-order corrections enter them differently.

Resonance locations and strengths

The locations of the low-order Lorentz resonances for Jupiter and Saturn according to equations (4) and (5) are given in Table 1, where we have taken $J_2 = 0.01473$, $J_4 = -0.00059$ and $R_J = 71,398$ km for Jupiter²³, and $J_2 = 0.01630$, $J_4 = -0.00092$ and $R_S = 60,330$ km for Saturn²⁴; J_4 is used only in computing R_{syn} but not in equations (4) and (5). In agreement with our earlier statement, we see that a vertical $k = +1$ resonance is not permitted; the horizontal $k = +1$ resonance has a solution that will lie within the surface of the planet unless the planet is unreasonably oblate and dense (J. J. Lissauer, personal communication).

Relative strengths for the various k resonances in the jovian and saturnian ring systems are also listed in Table 1. To represent the planetary magnetic fields we have used the Pioneer 10 (3I, 2E) model¹⁹ for Jupiter since that spacecraft traversed a nearly equatorial orbit in the region of interest, and the JGR80 model for Saturn^{25,26} as it is the only representation involving

Table 1 Locations and relative strengths of Lorentz resonances

Resonance order k	Jupiter ($1 R_J = 71,398$ km)		Saturn ($1 R_S = 60,330$ km)	
	Location r_k/R_J	Relative strength*	Location r_k/R_S	Relative strength*

* Based on equation (6), using r_k as given here and magnetic field coefficients estimated from refs 19, 26. The tabulated values are 10^4 times those computed from equation (6); so as to have non-dimensional results that can be compared, we have not included ΩR in equation (6) for Jupiter and have divided the Saturn result by ΩR of Jupiter.

† The appropriate magnetic field coefficients are unknown and are arbitrarily selected to be similar to the planet's octupole terms

$k = 3$ sectorial harmonics. The particular values for the spherical harmonic coefficients are not especially accurate, especially for the higher-order terms; in fact, the fields probably change over long times as does the Earth's. Nevertheless, we emphasize that although resonance *strengths* will vary, depending on the precise representation selected for the magnetic field (see refs. 18, 19), the resonance *locations* rely merely on the spatial periodicity of the field, which depends on the well-demonstrated adequacy of the spherical harmonic model.

Compared with Jupiter's gravitational attraction, the total Lorentz force magnitude at the k th resonance is $0.008 |1/(1-k)| (V/10 \text{ volt}) (\mu\text{m/s})^2 (2g \text{ cm}^{-3}/\rho)$, where s is the particle's radius and ρ is its mass density; this assumes that field emission does not limit the electric potential of the particle, for otherwise s would appear to the power -1 (refs 10, 16). The component driving the $k = +2$ Lorentz resonance is about one-tenth the total Lorentz force. At the other resonances further from the planet, electromagnetic forces are somewhat less important because the higher-order components of the magnetic field decrease more rapidly than gravity does and because the speed of the particle across the field is generally lower.

As with any simple resonance, a region surrounding the precise resonance location shows amplified motions because the frequency of the force nearly matches the natural frequency of the system's response. Figure 2b depicts this by plotting the response of the system to typical forcing terms across the region of Jupiter's ring; this response is $\sim S_k [n_k^2 - k^2(n_k - \Omega)^2]^{-1}$ for each of the components. Note that the low-order resonances are quite broad (for example, the resonant term for the $k = +2$ case is large throughout the region 1.3–1.5 R_J), whereas higher-order resonances are substantially narrower. We have confirmed the results described above through a numerical integration of the full equations of motion (see ref. 14).

Planetary ring form and resonances

A recent reanalysis^{10,12} of the Voyager jovian ring images has identified three components to the system (see Fig. 2a). The main ring has an abrupt (<200 km wide) outer boundary whose half-power point is at $1.8086 (\pm 0.0014) R_J$, just outside the

small satellite Adrastea's orbit (semi-major axis $a = 1.8065 R_J$). Its low optical depth ($\tau \approx 10^{-5}$ – 10^{-6}) means that particle-particle collisions are rare^{10,12}. As seen in the back-scattered light that emphasizes large bodies, the main ring is <30 km thick¹⁰. A vertically extended halo, symmetrical about the ring plane, starts exterior to the ill-defined inner edge of the main ring at $\sim 1.71 (\pm 0.01) R_J$, only to disappear somewhere between 1.3 and $1.4 R_J$. The optical depth of the halo is comparable with that of the main ring and the particle size distribution there, as in the main ring, is a power-law starting at a few tenths of a micrometre. The brightness of a newly-discovered 'gossamer' ring^{12,27} decreases linearly with distance from the main ring and has a mean value $\sim 5\%$ that of the main ring. It stretches perhaps as far out as Thebe ($a = 3.15 R_J$) before vanishing from sight; its only notable feature is a $\approx 20\%$ enhancement at R_{syn} .

Because gravitational resonances, as distinct from Lorentz resonances, are so important in defining the Saturn ring structure^{3,4}, we consider their possible connection to the form of Jupiter's ring. Potentially significant gravitational resonances include Amalthea's 5:3 resonances¹¹, which are very near the main jovian ring's outer edge and the orbit of Adrastea: using the formalism of Shu²⁰ with values of J_2 and J_4 given earlier, we locate the horizontal (or eccentricity) resonance at $1.8054 R_J$ and the vertical (or inclination) resonance at $1.8126 R_J$; the mixed resonance is at $1.8071 R_J$. The third of these lies marginally within the positional error of the outer ring edge. The 5:3 resonance is very weak because of the small size of Amalthea coupled with the second-order nature of this resonance; its strength is only $\sim 10^{-5}$ of Mimas's 2:1 resonance which defines the outer edge of Saturn's B ring at the Cassini division, and 3×10^{-5} of Janus's 7:6 resonance which prevents the outer edge of Saturn's A ring from spreading²⁸. Even weaker is Io's 6:1 resonance, which is nearby¹¹. In addition, these resonances are unlikely to be important as one should not expect density waves to be generated, nor the shepherding mechanism to work, in the ethereal Jovian ring¹⁰. More probably, the boundary of the jovian ring is determined by the radial extent to which collisional ejecta is shed from Adrastea¹⁰, before the debris starts to evolve inwards. Nevertheless, the possible connection of this weak resonance with the form of the ring bears close scrutiny during the forthcoming Galileo observations for, if verified, it would require a re-evaluation of the mechanism whereby resonances terminate rings²⁹. For completeness we point out that Callisto's apsidal resonance is located at $1.39 R_J$, in the general vicinity of the inner perimeter of the halo. Note that the embedded satellites Adrastea and Metis have many resonances throughout the main ring.

Lorentz resonances, probably because they act on small grains, seem to account for much of the structure of the jovian ring. The jovian ring halo seems to be bounded by the interior $k = +3$ and $k = +2$ resonances. The outer boundary is easily understood. The orbits of grains in the main ring are expected to evolve rapidly inwards towards the halo because of plasma drag¹⁰. Once particles drift into the resonance zone they receive repeated out-of-plane thrusts and are pushed onto inclined (vertically extended) orbits. All halo particles reside in the region between the $k = +2$ and $k = +3$ resonances (see Fig. 2b); their jumbled trajectories have substantial radial and vertical excursions^{14,15}. The ring may appear to vanish at the strong $k = +2$ resonance because (1) the inward-evolving particles are so widely dispersed, having been scattered by both the $k = +2$ and $k = +3$ resonances, or (2) their extremely large excursions produce collisions into the jovian atmosphere, or (3) the individual particles have by this point simply evanesced through sputtering by magnetospheric particles¹⁰.

As already discussed, the main ring's outer boundary is probably associated with Adrastea, and not with Lorentz resonances. Nevertheless, despite the motion induced by the $k = +1$ and $k = +2$ terms, the overlapping inner $k = +3$ and $k = +4$ resonances produce a deep relative minimum in this locality (see Fig. 2b). The reduced vertical displacements here mean that the ring particles are more densely packed; this may possibly allow them

Fig. 2 Jovian ring boundaries are compared with positions of some low-order Lorentz resonances. *a*, A cross-section of Jupiter's ring, as deduced by Showalter^{10,12}. The thin main ring is $\sim 20\times$ as bright as the newly discovered gossamer ring²⁷, whose only feature is a slight enhancement at synchronous orbit ($\odot$). The locations of the outer edge of the gossamer ring and the inner edge of the halo are not well determined. The precise cross-section and density distribution of the halo are poorly constrained. *b*, Responses to the low-order Lorentz force components across the region of the ring in arbitrary units. The $k = +2$ and $+3$ resonances seem to bound the halo, and the $k = -2$ resonance may limit the outer edge of the gossamer ring.

to reach great enough number densities so as to act collectively in shielding themselves from the ambient plasma^{10,12}. Interparticle shielding in a dusty plasma can be such that the average charge on any particle is substantially less than that carried by an isolated grain (whose electric potential would be approximately the plasma's kinetic energy)^{16,17,30}. This reduced charge further lessens vertical motions and augments interparticle shielding¹². Perhaps this process could account for the surprising thinness of the main ring.

The brightness enhancement at R_{syn} in the gossamer ring may have three causes. First, vertical motions resulting from Lorentz forces will be limited in this region, even for the very tiny motes in this ring²⁷, as resonant forces are very weak near R_{syn} where $k \rightarrow \infty$ (see equation (6) and Fig. 2b). For shallow viewing angles such as those used by Voyager, this produces an enhancement at R_{syn} . Second, plasma drag, the principal cause of orbital evolution, vanishes at this point: hence any particles created by micrometeoroid collisions in this region will remain, whereas detritus elsewhere will be continually dragged away from its source region²⁷. Lastly, magnetically dominated particles have a tendency to drift towards synchronous orbit because of systematic charge variations^{16,17} (D. A. Mendix, personal communication).

The $k = -2$ resonance is near where the gossamer ring disappears. Perhaps outwardly-evolving particles are vertically dispersed enough by this resonance to make the already faint ring indistinguishable from background.

Lorentz resonances are much less important for Saturn's rings than for those of Jupiter because strengths are substantially lower (Table 1): Saturn's magnetic field is weaker as well as more regular than Jupiter's, and relative velocities are generally less because the ring straddles R_{syn} and the orbital velocity at R_{syn} is lower. In addition, saturnian ring particles are usually much larger (except for restricted regions^{3,4,10}) and charges smaller³⁰ so that charge-to-mass ratios are low. Furthermore, in the main ring system, optical depths are high so that our calculations, which ignore collisions, are moot.

The (interior) $k = +4$ resonance for Saturn is close to the B/C ring boundary ($1.525 R_S$) whereas the (exterior) $k = -3$ resonance lies just within the A ring edge ($2.267 R_S$) and the Keeler

gap ($2.263 R_n$). The (inner) $k=+4$ resonance is close to the gravito-magnetic stability limit for charged, massless grains launched with Keplerian velocity at $1.525 R_n$ (ref. 31) and the place where the magnetic equilibrium surface becomes undefined at $1.56 R_n$ (ref. 32); these apply, however, to particles for which q/m is effectively infinite.

It seems then that some part of the jovian ring's form is dictated by a resonance phenomena, albeit one different than the usual gravitational resonance of celestial mechanics. The

new resonance mechanism described here acts on small charged grains when they orbit through a non-uniform magnetic field. Additional study of the nature of this resonance will advance our understanding of the operation of all resonances.

This research has been supported by NASA grant NAGW 310. We thank M. Talman and B. Boettcher for preparation of the manuscript and J. N. Cuzzi for critically reading an earlier draft. The Planetary Science Institute is a division of Science Applications International Corporation.

Strontium isotope evidence for preserved density stratification in the main zone of the Bushveld Complex, South Africa

Martin R. Sharpe

Institute for Geological Research on the Bushveld Complex, University of Pretoria, Hillcrest, Pretoria 0002, South Africa

The Bushveld Complex formed from two isotopically distinct magmas. Magma addition and mixing can be tracked by measuring initial strontium isotope ratios of cumulates. Rocks with ratios of 0.7065 lie below the lower 2.2 km of the main zone (ratio = 0.7085), whereas those with ratios of 0.7073 lie above it. This unit represents a liquid layer intruded into the density-stratified magma pile near the base of the chamber. The Merensky Reef was produced by mixing of the pile with underlying trapped liquid enriched in precious metals.

EVIDENCE is accumulating that the layered rocks of the Bushveld Complex are the products of fractional crystallization from two magma series and their mixtures¹⁻⁵. Field and laboratory investigations have helped detect early derivatives of these series in the suites of quenched marginal rocks and related sills. The end-members have yet to be discovered. The stratigraphically older series were derived from SiO₂- and MgO-rich magmas similar to olivine boninites⁶; rocks of the other series are tholeiites. The lineages are termed U and A because of their ultramafic (orthopyroxene) and anorthositic (plagioclase) rock products, respectively⁷. U magmas are represented by quenched micro-orthopyroxenites, rich in incompatible elements (Zr = 70-300 p.p.m., Rb = 20-50 p.p.m.), 900-1,600 p.p.m. Cr and initial Sr ratio (R_0 ; ⁸⁷Sr/⁸⁶Sr₂₀₅₀) of 0.703-0.705 (refs 8, 9; Table 1). The marginal rocks quenched from magmas with a large A component are two-pyroxene microgabbros with low contents of incompatible elements (Zr ~ 15, Rb ~ 2 p.p.m.), ~250 p.p.m. Cr and R_0 values of 0.7065-0.7077. Rocks with compositions intermediate between these two 'end-members' are most abundant along the margin of the upper critical zone (Fig. 1) and are petrographically microgabbroic.

It is important to understand the mechanism of addition of parental magmas to the Bushveld chamber, because recent hypotheses concerned with the origin of layered complexes draw heavily on density stratification as a possible means by which

layering can be generated. Competing, yet (in many cases) overlapping hypotheses demand attention. Irvine and co-workers^{7,10} propose that rock layers grow laterally from the walls of magma chambers at shallow angles. The composition of each rock unit is controlled by that of its parental liquid layer, which forms part of a density-stratified system consisting of many such layers. Thus, new magmas may be intruded into stratified chambers at levels consistent with their density. Another school of thought¹¹ believes that such intrusion may occur as a turbulent plume which entrains existing magmas, spreads out in a discrete layer and controls sulphide precipitation. Most other hypotheses (see refs 12, 13 and A. J. Naldrett *et al.*, manuscript in preparation) depend on the new addition of magma forming a separate layer within a developing intrusion, at some level where a stratified magma system would have an appropriate density to accommodate the new liquid.

Unfortunately, definitive evidence in support of mechanisms such as density stratification, double-diffusive convection, turbulent plumes or other fluid-dynamic hypotheses in magma chambers has not been available. Evidence for the first of these possibilities is lacking because liquid layers are thought to be quickly destroyed during the processes of fractional crystallization and mixing, especially if they are thin as has mostly been assumed. This article presents field, geochemical and isotope evidence from the eastern Bushveld Complex for a 'fossilized'

Fig. 1 Map of a portion of the eastern Bushveld Complex with a panel diagram from south to north along the contact region and stratigraphic column of the Bushveld Complex and Transvaal Sequence. Positions of sample traverses and gabbroic marginal rocks are annotated. Codes for lithologies follow ref. 1.

2-3-km thick layer of gabbroic magma within the 9-km thickness of layered rocks, which differentiated *in situ* with relatively minor mixing between the under- and overlying magma columns.

Geochemistry

Three hundred and fifty cumulate rock samples were collected from the eastern Transvaal and analysed by X-ray fluorescence

for major elements and 19 trace elements as part of a comprehensive study of the layered rocks of the eastern Bushveld Complex (see ref. 1 for analytical procedures). Fifty-five of these samples were analysed for Sr isotopes. Samples were selected to provide ample vertical coverage of the layered sequence, representative collections from each zone or group of petrographically related rocks and detailed coverage across important boundaries where

Fig. 2 Whole-rock geochemical data from 300 m below the Merensky Reef in subzone B of the critical zone to 300 m above the pyroxenite marker in subzone C of the main zone. Normative cumulus minerals: ch, chromite; mt, magnetite (above Merensky Reef); cpx, clinopyroxene; opx, orthopyroxene; pl, plagioclase; ol, olivine (Fe-rich); Q, quartz.

there are major changes in the cumulate parageneses. Thirty marginal rocks spanning the lower 5.5 km of the complex were also analysed (N. M. Evensen, B. V. Rao and M. R. S., in preparation). Concentrations of Rb and Sr were determined by isotope dilution.

The region of greatest interest lies between the Merensky Reef and the 'pyroxenite marker'^{14,15}, and comprises subzones A and B of the main zone (Fig. 2). In many respects, the main zone is an anachronism in the evolution of the complex. Its relatively homogeneous, two-pyroxene gabbros contrast in composition and lithology with the strongly layered units of the upper critical zone and the equally well-layered upper zone, which lie below and above, respectively. In the critical zone, the platinum group element (PGE) tenor of mineralized layers increases upwards, to climax in the UG2 chromitite layer and the Merensky Reef (Fig. 1). In the upper zone, abundant cumulus magnetite precipitated along with orthopyroxene, clinopyroxene and plagioclase, with Fe-rich olivine occurring at later stages. Whole-rock samples beneath the Main Magnetite Layer contain up to 5.6 p.p.m. total PGE¹⁶, with an average concentration of ~1.3 p.p.m.¹⁷.

Plots of norms, mineral compositions, some trace elements and Sr/Al ratio against stratigraphic height for subzones A and B of the main zone show major breaks at the base and top of this interval (Fig. 2). Discontinuities in the Pt/(Pt+Pd) ratio at the same levels were interpreted as evidence for addition of new magma¹⁷. At the pyroxenite marker the intruding liquid was 'replenished' in PGE, because the main zone is relatively dep-

leted compared with the critical and upper zones. The marker was originally considered as the expression of addition of fresh magma^{14,15}, even though supporting field relations like cross-cutting layers and footwall disturbances are ill-exposed or lacking in the eastern Bushveld. At the level of the Merensky Reef, however, there is much field^{1,9} and geochemical^{8,18} evidence for intrusion of new magma.

The lower 200 m of the main zone is lithologically variable. In the eastern Bushveld, the En content of orthopyroxene increases by up to 15 mol % in this interval (Fig. 2). Upward trends are fairly smooth, suggesting that simple fractional crystallization, with perhaps local addition of fresh magma (such as at the upper mottled anorthosite, Fig. 2) gave rise to gradually evolving profiles. Differentiation trends begin a marked reversal 300–500 m below the pyroxenite marker, but are most pronounced within metres of this layer. Other compositional tracers mirror these paths. Were subzones A and B of the main zone to be removed from the Bushveld Complex, it appears that the post-Merensky Reef and sub-pyroxenite marker compositions would prescribe a continuous trend, with only minor discontinuities between their whole-rock compositions. I suggest that this packet is an aberration on the normal fractionation sequence of critical zone to subzone C of the main zone and then upper zone. The petrographic and whole-rock composition suggests that the packet is a thick layer of liquid A that was intruded into the Bushveld chamber near its base, which has been preserved simply because of its thickness. However, mixing did occur at its lower and upper boundaries.

Fig. 3 $^{87}\text{Sr}/^{86}\text{Sr}$ at 2,050 Myr against stratigraphic height for the traverses and marginal rocks detailed in Fig. 1. Enlarged boxes show detail at the Merensky Reef and pyroxenite marker. Italicized mineral names are at levels of their addition (+) or deletion (-) from the cumulus assemblage.

Strontium isotope systematics

The Rb/Sr isotope age of the Bushveld layered rocks is 2,050 Myr. Early work gave an age of $1,954 \pm 30$ Myr on 13 samples²⁰, and Hamilton⁸ reported an average age of $2,095 \pm 24$ Myr. Both used the ^{87}Rb decay constant of $1.39 \times 10^{-11} \text{ yr}^{-1}$. Re-calculation of Hamilton's data with $\lambda^{87}\text{Rb} = 1.42 \times 10^{-11} \text{ yr}^{-1}$ gives an age of 2,050 Myr⁹. Unfortunately, because two magma types of differing R_0 are represented in the layered rocks, average ages such as these are less relevant than data from units of layered rocks which were derived from one or other of the magma types, or a stable mixture between them. Isochron ages of 2,048–2,057 Myr were acquired from sample sets from the lower zone, subzones A and B of the main zone, and the upper zone (M.R.S. *et al.*, in preparation). A neodymium age of $2,055 \pm 155$ Myr is reported by M.R.S. *et al.*, (in preparation). It seems that any Rb and Sr mobility must have operated homogeneously over cubic kilometre scales and is thus unlikely. The age of the

complex is also constrained by isotope age-dating of rock units from the Transvaal Sequence into which the complex is intruded, and the Bushveld granite, which cuts the layered rocks. The most recent data have been compiled by von Gruenewaldt *et al.*¹⁹.

All Bushveld marginal rocks have R_0 values higher than expected from normal mantle (Rb/Sr = 0.03) at 2,050 Myr; the values range from 0.704 (U > A) to 0.7077 (A > U). Layered rocks have a wider range (0.704–0.7086). Such high values might originate in various ways, such as contamination on local or regional scales or Rb mantle enrichment. A brief treatment of Bushveld magma evolution is described here. Contamination of magmas has been proposed on the bases of trace element and isotope data^{1,3,8,9,20}. Because the R_0 ranges of marginal rocks, and cumulates are approximately the same, local contamination of magmas in the chamber after quenching of the marginal rocks is considered unlikely. Regional contamination, however, is more probable, especially for the main zone, where values up

Samples CO-211 and CO-073 are close to the end-member compositions, CO-114 is a fractionated derivative of U mixed with high- R_0 A liquid; CO-071 is A mixed with some fractionated liquid U. Analyses summed to 100% anhydrous; all Fe as FeO; ND, not determined; Eu*, chondrite-normalized Eu anomaly; R_0 , ($^{87}\text{Sr}/^{86}\text{Sr}$)_{2,050} (ref. 9 and M.R.S. *et al.*, in preparation); rare-earth element data from M.R.S. and M. P. Gorton (unpublished data). Blz, adjacent to lower zone; Bcza, adjacent to lower critical zone; Bczb, adjacent to upper critical zone; Bmz, adjacent to main zone.

to 0.7086 exceed those of possible local contaminants like the Rooiberg felsites ($R_0 < 0.708$; R. E. Harmer, personal communication). However, Pretoria Group shales²¹ have initial ratios between 0.708 and 0.723 (ref. 9) and so may be more likely candidates. Combined Nd and Sr isotope data (M.R.S. *et al.*, in preparation) indicate that both U and A magmas lie in the enriched quadrant of a $\epsilon_{\text{Nd}}/\epsilon_{\text{Sr}}$ plot. The U dominant rocks lie closer to the "Bulk Earth" composition, but increasing amounts of A drives points diagonally from the fulcrum towards $\epsilon_{\text{Sr}} = 150$, $\epsilon_{\text{Nd}} = -20$, typical of crustal material²². Thus, relatively homogeneous contamination on scales of hundreds of thousands of cubic kilometres is indicated.

The addition of liquid A to the Bushveld magma chamber has been monitored by making use of the widely contrasting R_0 values of the U and A magma series (ref. 9 and M.R.S. *et al.*, in preparation). The Sr isotope data provide confirmation of the unusual character of the main zone (Fig. 3). R_0 values of cumulates increase from 0.7065 immediately below the Merensky Reef to 0.7085 about 200 m into subzone A of the main zone. The increase in R_0 across the Merensky Unit is sudden. It was first noted by Kruger and Marsh¹⁸ and equated with an addition of new magma with high R_0 . Geochemical parameters through the first 2.2 km of the main zone (Fig. 2) prescribe a trend suggestive of steadily increasing fractionation, on which broad cyclic sweeps are superimposed, particularly evident in the Co data. Samples from subzone A of the main zone have constant R_0 values, regardless of the irregularities in the trends. In subzone B, which has somewhat more regular data for Co, the isotope data show local decreases. I do not dismiss the possibility, however, that high R_0 magma was added intermittently within the main zone. In the limitations of sample

Fig. 4 Variation in liquid density in relation to temperature for Bushveld parental magmas at 5 kbar. The range of densities expected in the chamber are controlled by initial densities (points U_0 and A_0), upon which are superimposed the effects of fractional crystallization of different minerals. The crystallization of orthopyroxene from U liquids along path (U_0-U_3 , where subscript refers to derivative type) will decrease liquid density until plagioclase begins to crystallize (near U_2), whereupon density increases, assisted by late-stage iron enrichment. A liquids increase in density with temperature drop during plagioclase crystallization (path A). At 1,330 °C (CO-114 liquidus temperature at 1 atm⁵ + 10 °C kbar⁻¹) the chamber might be expected to contain liquids with a wide range of densities, comprising U derivatives, superheated A derivatives and A + U mixtures, located along line L_1 . Further temperature drop will increase that range through L_2 to L_3 . New liquids could readily be accommodated at levels controlled by their densities, like at point A_0 , in the middle of the density range (solid arrow). Thick line A+U represents the temperature/density range over which U derivatives and superheated A derivatives might finger mix; thin dashed lines are superheating paths for A derivatives.

coverage, values of R_0 remain approximately steady through the bulk of the main zone, although slight fluctuations do begin 300–500 m below the pyroxenite marker, where other indices also become perturbed. At the same distance below the marker, R_0 decreases to 0.708, but the most marked decrease, to 0.7073, occurs within a 25-m interval centred on the marker. The R_0 remains at ~0.7073 through the rest of the complex.

These data show that the main zone represents a slab of layered cumulates that were derived from high R_0 liquid. Its basal portions mixed with the underlying post-Merensky Reef U + A residuum to produce a steep R_0 gradient. Similarly, the less rapid R_0 drop at the top of subzone B can be equated with deeper penetration of the front along which A and A + U magmas mixed. Possibly the pyroxenite marker might be considered as a sort of semipermeable membrane along the interface between 'old' and 'new' magmas. The post-Merensky Reef and pyroxenite marker R_0 values are almost contiguous: the difference of 0.0005 between the 0.7065 value at the Merensky Reef and 0.707 at the pyroxenite marker may be ascribed to upward transfer of some A residuum from the crystallizing subzones A and B of the main zone.

Mass-balance calculations can be made to determine U:A ratios at the time of formation of the Merensky Reef and the upper zone, assuming no local contamination further affected

$^{87}\text{Sr}/^{86}\text{Sr}$ ratios are given at the 1 σ level. Analyses of NBS-987 are reported as 0.71026 $\pm$ 3 (1 σ). Boxed samples: Merensky Reef (PB1-1332) and pyroxenite marker (BDS-66).

the regionally contaminated magmas. The crystallization rate and bulk D of the rocks below the Merensky Reef cannot be estimated at present without excessive speculation. It is assumed that U liquids had $R_0 \sim 0.704$ and Sr = 167 p.p.m. (sample CO-211; ref. 9), quenched liquids at the top of the critical zone have $R_0 = 0.7065$ and Sr = 330 p.p.m. (CO-250; ref. 9) and quenched liquids from which the upper zone crystallized had $R_0 = 0.707$ with Sr = 380 p.p.m. (CO-052). The pure A liquids (main zone) had $R_0 \sim 0.7085$ and high Sr (>450 p.p.m.). Using the equations of De Paolo²³, adapted for simple mixing, it can be calculated that the Merensky Reef crystallized from a total mixture of 88% U + 12% A. A further 25% of fractionated A residuum added to the elevated Merensky Reef source magma simulates the R_0 of the upper zone, which crystallized from a total U:A mixture of 71:29.

Isotope relations

Cumulates of subzones A and B in the main zone have $R_0 \sim 0.7085$ (Fig. 3). The marginal rocks that occur along the basal contact of the main zone (Fig. 1) have $R_0 = 0.706\text{--}0.7075$ (ref. 9). The isotope ratios of marginal and main zone layered rocks are completely out of equilibrium. The marginal rock ratios closely resemble those of layered rocks from the upper critical zone (0.7061–0.7065; Table 2) and the upper zone (0.7073). They

are probably the quenched equivalents of the magma(s) that occupied the chamber at Merensky Reef times. Derivatives of these magmas, modified at a later stage by addition of main zone residual liquids, crystallized rocks that now occur ~3 km higher in the succession.

The marginal rocks along the basal contact of the main zone occur as a thin tenuous swath, some 10% of the extent of the upper critical zone marginal zone. Field relations⁹ suggest that the intrusion of A liquids that were to give rise to the main zone practically destroyed the original marginal rocks and replated the basal margin with some high- R_0 material. Two marginal rock generations occur south of the Laersdrif Fault (Fig. 1), where magnetite-rich microgabbros are intruded by fine-grained, two-pyroxene gabbro sheets (J. Schweitzer, personal communication).

Density considerations

The lower subzones of the main zone crystallized as a sheet from A liquids that were added in copious amounts to the Bushveld magma chamber, which was, at the time, crystallizing the upper critical zone from U >> A liquids. The massive addition of A liquid occurred near the base of the chamber, at a level consistent with its density. The magmas in the chamber were relatively hot yet dense; A magmas were cooler and slightly less

dense. The A sheet underwent limited mixing at its base with fractionated U+A mixture, giving rise to the steep R_0 gradient. The fact that the Merensky Reef is located at this level is surely more than coincidence, even though precious metals were steadily concentrated in residual magmas during formation of the lower and critical zones²⁴, as also shown by upward increases in the PGE tenor of the chromitite layers. I argue that evolution of the Merensky Reef is inextricably bound to the addition of A magma.

I performed melting experiments on rocks considered to be quenched $U \gg A$ (CO-114) and $A \gg U$ (CO-071) mixtures⁵ (Table 1). Their liquidus temperatures were 1,275 and 1,210 °C, respectively. The amount of chromite precipitated on mixing two such magmas depends on their proportions and differences in fO_2 (ref. 5). Because the critical zone contains abundant chromitite layers up to 1.6 m thick and mineral compositional variations across such layers are relatively minor (C. J. Hatton, unpublished data), it can be assumed that the volumes of magma A intermittently added to the magma chamber were small (supported by the isotope data), but their oxygen fugacities were very different. The pre-Merensky Reef rocks retain evidence of continuous sulphur saturation of the parental magmas²⁴, yet sulphides in the main zone are extremely rare. The bulk compositions of A and U magmas were dissimilar. Addition of 2–3 km of magma A would have increased pressures at the top of the critical zone by ~1 kbar. I suggest that the changes in T , P , X , fO_2 and fS_2 imposed on the trapped packet of U+A magma mixtures from which the upper critical zone was crystallizing were sufficient to stimulate the rapid precipitation of olivine and sulphides rich in precious metals, so giving rise to the Merensky Reef.

At the top of the A sheet, the cool dense A was overlain by hotter, less dense 88% U+12% A, stable conditions ideally suitable for diffusive mixing. Less dense fractionated residual from crystallization of the A sheet were added to the overlying magma column, causing the downward migration of the interface controlled simply by volume changes and mass diffusion. The liquids lying above the pyroxenite marker were homogenized to $R_0 = 0.7073$. Perhaps the abundant upper zone magnetite (~10 modal %) is a signature of the upward transfer of Fe-enriched residual material.

Density relations of some members of the U and A families have been investigated²⁵. Figure 4 represents conditions in the magma chamber at 5 kbar pressure²⁶ before intrusion of A liquids. Liquids with different densities would be present, density contrasts having a greater range with falling temperature. New A_0 liquid or its derivatives could intrude readily the stratified pile at a level controlled by its density, and elevate the superincumbent liquid column, still enriched in precious metals, by 2–3 km.

Conclusions

Subzones A and B of the eastern Bushveld Complex represent a frozen interval in its evolution, where a massive inflow of gabbroic liquid into the magma chamber, at a level consistent with its density, split the crystallizing column of U+A liquids. Figure 5 describes the strontium isotope evolution of the eastern Bushveld Complex by a scheme of magma addition and mixing. In simple terms, the elevation of the post-Merensky Reef residuum gave rise, with later mixing at the top of the A sheet, to the pyroxenite marker, subzone C of the main zone and the upper zone. Mixing at the base of the sheet was over a 200–300-m interval, which created a pronounced R_0 gradient, along with lithological and compositional fluctuations. Marginal rocks with isotope ratios out of equilibrium with adjoining cumulates attest to this intrusion mechanism. Minor addition of A liquids occurred in the crystallizing sheet. Thus, the magma generation and intrusion chronology of the Bushveld Complex is simplified and Occam's razor rediscovered.

This is the first evidence of fossilized density stratification in a large layered intrusion. It provides strong evidence that double-diffusive convection and magma mixing were important processes in the evolution of the Bushveld Complex.

Fig. 5 Diagram of the possible sequence of events that gave rise to the Sr isotope profile of the eastern Bushveld complex (M.R.S. *et al.*, in preparation). *a*, U₀ magmas are intruded into the chamber and differentiate, giving cumulates, U derivatives and related sills with primitive R_0 (0.703–0.704). *b*, Addition of A₀ liquids commences during lower critical zone times, with major addition at subzone A–B boundary. R_0 in cumulates and residual U >> A mixtures increases steadily to 0.7065. Sills of U+A magmas are intruded into the floor rocks. *c*, Massive addition of A₀ occurs near the base of the chamber and splits the U+A liquid pile. Mixing with basal trapped liquid makes the Merensky Reef. The proto-pyroxenite marker forms. The R_0 of precipitating cumulates increases dramatically to 0.7085. *d*, Crystallization of the A sheet continues. Transfer across the proto-pyroxenite marker decreases in cumulates of subzone B to 0.708 and increases R_0 in subzone C of the main zone and the upper zone to 0.7073.

I thank T. N. Irvine for inspiration and corroboration. Most isotope data presented here were acquired at the University of Toronto. I thank C. A. Lee, N. M. Evensen and A. J. Naldrett for discussions, and my colleagues G. von Gruenewaldt,

C. J. Hatton and R. E. Harmer for examination of the text. Constructive criticism by A. J. Erlank and W. M. White is acknowledged. The figures were drafted by Mrs S. J. M. Potgieter.

Identification of serotonin M-receptor subtypes and their specific blockade by a new class of drugs

B. P. Richardson, G. Engel, P. Donatsch & P. A. Stadler*

Preclinical Research Department, Sandoz Ltd, CH-4002 Basel, Switzerland

We describe a new class of drugs that selectively block serotonin M-receptors on peripheral neurones. Because of their high affinity, some of these drugs are the most potent of any pharmacological class yet reported. They have allowed the identification of three M-receptor subtypes, one of which is responsible for mediating the painful effects of serotonin in humans.

GADDUM and co-workers suggested the existence of different serotonin (5-hydroxytryptamine, 5-HT) receptor subtypes when they showed that this substance contracts the guinea pig ileum by two different mechanisms: a direct action on the smooth muscle and an indirect action mediated by the release of acetylcholine from parasympathetic nerve endings. Because the former mechanism was blocked by dibenzylamine (D) and the latter by morphine (M), the excitatory 5-HT receptors on smooth muscle and parasympathetic nerve endings were designated D- and M-receptors respectively^{1,2}. Neither dibenzylamine nor morphine is selective or potent in its antagonism of 5-HT. In fact morphine prevents the indirect contractile action of 5-HT in this preparation not by a specific blockade of neuronally located receptors, but by a non-selective inhibition of acetylcholine release^{3,4}.

Although many potent new 5-HT antagonists for smooth muscle D-receptors have subsequently become available, they are all completely inactive at M-receptors located on peripheral neurones. Some structural analogues of (-)-cocaine, which inhibits the neuronal actions of 5-HT on the guinea pig ileum^{1,2,5} and sympathetic ganglia^{6,7}, and metoclopramide behave as competitive antagonists at these sites⁸⁻¹¹. These compounds, however, have several other pharmacological properties and display only limited potency and selectivity for M-receptors^{10,12,13}. Thus, despite the wide distribution of excitatory 5-HT receptors in the peripheral nervous system¹⁴, their pharmacological and functional characterization has been greatly hindered by the lack of potent, selective agonists and antagonists. We have adopted an approach analogous to that originally used for generating selective antagonists for β -adrenoreceptors and histamine H₂-receptors: the naturally occurring ligand, in this case 5-HT, was used as the starting point for chemical derivation¹⁵⁻¹⁷. Highly selective agonists for either D- or M-receptors were synthesized and extremely potent and selective antagonists of

neuronal 5-HT M-receptors were produced. Large differences in the affinity constants obtained for these antagonists on different isolated tissues containing neuronal excitatory 5-HT receptors show that there are at least three pharmacologically distinguishable M-receptor subtypes. Preliminary reports of some of these findings have been reported elsewhere¹⁸.

Assay systems

Quantitative responses to the newly synthesized 5-HT analogues were routinely obtained in six different *in vitro* assay systems. A minimum of three independent experiments were conducted for each compound and complete concentration-response curves were constructed. To assess their affinity for M-receptors three bioassays were used: the de-sheathed rabbit vagus nerve, the isolated rabbit heart, and the guinea pig ileum incubated in the presence of 10⁻⁶ M methysergide (see Figs 1, 2 legends). In the first two assay systems 5-HT D-receptor antagonists, such as methysergide (10⁻⁵ M, *n* = 3, data not shown), have no influence on the action of 5-HT and in the third assay, using guinea pig ileum, 10⁻⁶ M methysergide is continuously present to abolish the direct action of 5-HT on the smooth muscle D-receptors present in this preparation. We also used three non-M-receptor systems. Contractile responses of rat uterine strips were used to assess the affinity of compounds to smooth muscle 5-HT D-receptors. In addition, displacement of the specific binding of [³H]5-HT or 2-[¹²⁵I]doxylsergic acid diethylamide ([¹²⁵I]LSD) from rat cortex membranes was used for measuring the affinity of compounds to central 5-HT₁ and 5-HT₂ receptors, respectively^{19,20}.

Selective agonists for M- and D-receptors

Our initial chemical programme was based on the assumption that different conformations of the 5-HT molecule are required for activation of M- and D-receptors. By systematic methyl substitutions in the indole nucleus and ethylamine side chain we attempted to reduce the conformational freedom of the 5-HT

* Deceased

Fig. 1 Agonist potency of methylated 5-HT analogues relative to 5-HT (potency = 1.0) on the de-sheathed rabbit vagus nerve (open columns) and the rat uterus (striped columns). Each column indicates the geometric mean value obtained from at least three independent experiments. Vertical lines on each column indicate 90% confidence limits.

Methods. Isolated rabbit vagus nerve. New Zealand White or Yellow Silver male or female rabbits weighing 3.0–4.0 kg were killed by the intravenous injection of pentobarbital. Both vagi were dissected out, de-sheathed (that is, epineurium removed) and placed in a small compartmentalized Perspex chamber containing physiological salt solution as described previously^{37,38}. Extracellular recordings of the compound action potential were made so that the amplitude of the action potential in both myelinated (α and $\alpha\beta$) and non-myelinated (C) fibres could be recorded separately³⁸. 5-HT caused a dose-dependent reduction in the amplitude of the 'C' fibre action potential at concentrations between 3.5×10^{-7} and 2.5×10^{-6} M without affecting the amplitude of the action potential carried in the faster-conducting α and $\alpha\beta$ fibres. The maximal reduction in the 'C' fibre action potential amplitude caused by 5-HT was $45 \pm 0.4\%$ ($n = 35$), indicating that a subpopulation of 'C' fibres is preferentially affected by 5-HT. Based on these results, 45% reduction in amplitude was considered the 'maximal' (100%) effect. The relative potency of the methylated analogues was measured by running a full cumulative concentration-response curve for 5-HT first and then washing out 5-HT for as long as required for the amplitude of the 'C' fibre action potential to return to its original value (usually 30–40 min). The contact time for each concentration of agonist was 15 min. Methylated analogues were tested subsequently in the same way. Their potencies relative to 5-HT at 50% of the maximum 5-HT effect were then assessed from these dose-response curves for each experiment. Each analogue was tested for antagonistic action of the 5-HT effect by combining the highest concentration which produced no agonist action on its own with 1.5×10^{-6} M 5-HT. None of the analogues had antagonist action when tested in this way. To demonstrate that the reduction in amplitude of the 'C' fibre action potential caused by each of these analogues really resulted from a stimulation of 5-HT M-receptors and not from some other mechanism, the ability of a selective 5-HT M-receptor antagonist to block a maximally effective concentration of each analogue was tested, as such antagonists became available. The agonist action of all analogues was blocked by prior incubation of the nerve with ICS 205-930 (10^{-8} M) for 30 min ($n = 4$). Isolated rat uterus. To study the action of these analogues on D-receptors, isolated uterine strips from oestrogen-treated rats were used as previously described³⁹. Full concentration-response curves for the contractile action of 5-HT were constructed in each case (3×10^{-9} – 3×10^{-6} M). Uteri that did not respond to 10^{-8} M 5-HT were discarded. When the concentration of 5-HT producing a maximal contraction had been established, it was washed out and the methylated analogue tested in the same way. The relative potencies of the methylated analogues were again estimated from the dose-response curves at 50% of the maximal 5-HT effect. As in the vagus nerve, each analogue was tested for antagonism of the 5-HT effect by combining the highest concentration which produced no agonist action on its own with 10^{-6} M 5-HT. None of the analogues had antagonist action when tested in this way. The agonist action of each of the methylated analogues was abolished by prior incubation of the muscle strips with methysergide (10^{-6} M) for 30 min ($n = 6$).

molecule and thereby create analogues with increased specificity for one of these receptors.

Figure 1 shows that this strategy indeed provided highly selective D- and M-agonists. For instance, 2-methyl-5-HT is 2,000 times less potent than 5-HT as an agonist at D-receptors in the rat uterus and yet still possesses ~50% of the potency relative to 5-HT at M-receptors in the vagus nerve. Conversely, S(+)-α-methyl-5-HT has ~50% of the potency of 5-HT in the uterus, but is ~770 times less potent than 5-HT in the vagus nerve.

These two compounds were tested in the other four assay systems (Table 1). The 2-methyl analogue possesses ~50% of the potency of 5-HT on two other M-receptor systems, the rabbit heart and guinea pig ileum. There was no statistically significant difference between the relative potencies of this compound on the three M-receptor systems, indicating that these receptors may be identical. However, the data obtained with S(+)-α-

methyl-5-HT suggests otherwise. Although this compound showed greatly reduced potency relative to 5-HT on all three M-receptor assays, there were differences between the values obtained in each system. Thus, S(+)-α-methyl-5-HT was 770 times less potent than 5-HT on the vagus, 22 times less potent on the heart and only ~11 times less potent on the ileum. Subsequent work with competitive antagonists, as indicated below, confirmed that there are indeed different subtypes of M-receptors in these three tissues.

Radioligand binding data show that the affinity of S(+)-α-methyl-5-HT and 2-methyl-5-HT to 5-HT₁ receptors was ~34 and 370 times, respectively, less than that of 5-HT itself, indicating that these receptors are different from both the D- and M-types (Table 1 and ref. 19). S(+)-α-methyl-5-HT had an affinity similar to that of 5-HT in both the uterus and the competition binding studies using [¹²⁵I]LSD in rat cerebral cortex membranes, whereas 2-methyl-5-HT was devoid of

Table 1 Agonist potency of methylated 5-HT analogues relative to 5-HT (=100)

	Vagus nerve	M-receptors Heart	Ileum	D-receptors Uterus	Cortex-binding sites	
					5-HT ₁	5-HT ₂
5-HT	100	100	100	100	100	100
S(+)-α-methyl-5-HT	0.13 (0.10–0.16)	4.6 (2.8–7.4)	8.9 (5.3–14.9)	49.1 (35.5–67.9)	2.9 (2.5–3.2)	83.5 (56.9–122)
2-Methyl-5-HT	47.3 (41.1–54.5)	52.6 (42.4–65.3)	44.8 (31.8–63.1)	0.05 (0.01–0.07)	0.27 (0.24–0.29)	3.5 (1.5–7.9)

Values are geometric means with 90% confidence limits obtained from a minimum of three independent assays. Methods for estimation of the relative potencies of analogues on the rabbit vagus nerve and rat uterus are given in Fig. 1 legend. Methods for measuring affinities to neuronal 5-HT receptors in the rabbit heart, guinea pig ileum and rat cortex membranes have been published previously^{19,20,34}.

Fig. 2 5-HT concentration-response curves in the presence and absence of competitive M-receptor antagonists. *a*, Rabbit vagus nerve; *b*, rabbit heart; *c*, guinea pig ileum. *a*, Ability of 5-HT to cause a reduction in the amplitude of the 'C' fibre action potential in the absence of antagonist (●) and after prior equilibration of the nerve with compound I (see Table 2) at concentrations of 2×10^{-13} M (○), 10^{-12} M (□) and 5×10^{-12} M (*); $n=4$ in each case. In a separate series of experiments, it was shown that, unlike compound I, the 5-HT D-receptor antagonist methysergide (10^{-5} M) did not influence the 5-HT concentration-response curve in this tissue ($n=3$, data not shown). *b*, Positive chronotropic effect of 5-HT in the absence of antagonist (●; $n=9$) and after prior equilibration of the heart with compound II (see Table 2) at concentrations of 3×10^{-10} M (○; $n=5$) and 10^{-9} M (□; $n=7$). Unlike compound II, methysergide (10^{-5} M) had no effect on the 5-HT concentration-response curve in this tissue ($n=3$, data not shown). *c*, Contractile action of 5-HT in the absence (●) and presence of compound III (see Table 2) at concentrations of 10^{-8} M (○), 3×10^{-8} M (□) and 10^{-7} M (*); $n=4$ in each case. Vertical bars indicate the s.e.m. in each case.

Methods. *a*, In each tissue a cumulative concentration-response curve to 5-HT was established initially, as described in Fig. 1 legend. After washing out the agonist, the nerve was equilibrated with a set concentration of compound I for 60 min and the concentration-response curve to 5-HT was then repeated in the continued presence of the same concentration of compound I. When a concentration of 5-HT sufficient to produce a maximum effect had been applied, the antagonist combination was washed out, the nerve equilibrated for 60 min with a higher concentration of antagonist and the procedure repeated. *b*, Isolated rabbit hearts were perfused by the Langendorff technique and concentration-response curves were constructed for 5-HT in the absence and presence of compound II as described previously⁹. The antagonist was allowed to equilibrate with the tissue for 30 min before repeating the 5-HT concentration-response curves in the continued presence of the same concentration of antagonist. *c*, Concentration-response curves for the contractile action of 5-HT in the presence and absence of compound III were conducted in the guinea pig ileum incubated with 10^{-6} M methysergide as described previously¹⁰. The antagonist was permitted to equilibrate with the ileum for 30 min before repeating the concentration-response curves in the continued presence of the same concentration of antagonist.

relevant effects in either system. Thus, 5-HT₂ receptors in rat cortex are different from M-receptors found on peripheral neurones, although they may be similar to D-receptors found in the uterus and other smooth muscle preparations²¹.

M-receptor antagonists

Our results show that 2-methyl-5-HT and *S*(+)- α -methyl-5-HT are selective M- and D-receptor agonists, respectively. We next attempted to synthesize analogues of 5-HT that retained their affinity and selectivity for M-receptors but that lacked intrinsic activity; in other words, compounds that could occupy these receptors without activating them. Such compounds should behave as competitive antagonists of 5-HT at M- but not D-receptors. By extending the ethylamine chain of 5-HT and making rigid analogues where the terminal nitrogen was included in a tropine or homotropine ring system (see Table 2), we obtained a large series of competitive M-receptor antagonists, with remarkably high affinity and selectivity. Such compounds behave as true competitive 5-HT antagonists on all three M-receptor systems (Fig. 2; Table 2). However, the pA_2 values obtained for compound I (3- α -homotropanyl)-1-methyl-5-fluoroindole-3-carboxylic acid ester or those for compound II (*N*-desmethyl-3- α -homotropanyl)-1-*H*-indole-3-carboxylic acid ester) differed significantly from tissue to tissue ($P < 0.01$, paired *t*-test), indicating that the M-receptors in the vagus, heart and ileum are not identical. Thus, compound I is a highly selective antagonist for the type of M-receptor found in the vagus nerve, whereas compound II shows selectivity for that found in the heart. Both compounds yielded significantly lower pA_2 values for the M-receptors in the guinea pig ileum than for those in

either the vagus or heart, showing the presence of a third type of M-receptor in this tissue. The conclusion that the M-receptors in the ileum and heart differ from one another is in agreement with that of earlier studies where (-)-norcocaine also yielded significantly different pA_2 values in these tissues¹¹. None of the M-antagonists so far synthesized has shown appreciable affinity for uterine D-receptors or for 5-HT₁ or 5-HT₂ receptors in the rat cortex ($pK_D < 5.0$ in all three systems, $n=3$).

As M-antagonists became available, we also tested the selective M-receptor agonist, 2-methyl-5-HT, against them to check that the effects of this agonist in the vagus, heart and ileum were the consequence of M-receptor activation. As shown in Table 2, the pA_2 values obtained were not statistically different ($P > 0.05$, paired *t*-test) from those using 5-HT as agonist, showing that both agonists stimulate a common receptor in each tissue, despite the fact that a different subset of these receptors is found in each of the three tissues, as indicated above. Thus, both 5-HT and 2-methyl-5-HT have full agonist action at each of the three M-receptor subtypes.

The third antagonist listed in Table 2, (3 α -tropanyl)-1-*H*-indole-3-carboxylic acid ester, termed ICS 205-930, is a compound with similar affinity for both the M-receptors in the vagus nerve and for those in the heart, but again shows lower affinity on the ileum. This compound has negligible affinity for uterine D-receptors or for 5-HT₁ or 5-HT₂ receptors in the rat cortex. In a series of ligand binding assays it was also demonstrated that this compound lacks affinity ($pK_D < 6.0$) for α_1 , α_2 , β_1 or β_2 adrenoreceptors, D-1 or D-2 dopamine receptors, H₁ histamine receptors, muscarinic receptors or benzodiazepine receptors (data not shown). This makes ICS 205-930 a potent and selective 5-HT M-receptor antagonist.

Actions of M-receptor antagonists

A bolus injection of 5-HT into the jugular vein of anaesthetized rats induces a vagally mediated reflex bradycardia²². This effect, the von Bezold-Jarisch reflex, can be elicited in several species by various compounds which stimulate sensory nerve endings located in the wall of the right ventricle²³. Recent studies have shown that both metoclopramide and several cocaine analogues can block the 5-HT-induced von Bezold-Jarisch reflex because, in addition to their various other pharmacological properties, they act as neuronal 5-HT receptor antagonists^{24,25}. Consistent with the mediation of this 5-HT effect being through M-receptor activation is the finding that the reflex can also be elicited by the selective M-receptor agonist 2-methyl-5-HT at doses as low as 5 µg per kg (see Fig. 3a), but not by the selective D-receptor agonist *S*(+)- α -methyl-5-HT at doses as high as 1,000 µg kg⁻¹ (*n* = 5), and that the ability of 5-HT to induce the von Bezold-Jarisch reflex is not prevented by pretreatment of the rats with the D-receptor antagonist methysergide (Fig. 3b). In contrast, an intravenous dose of 1 µg per kg of the selective M-receptor antagonist ICS 205-930 caused a parallel rightward shift of the 5-HT dose-response curve, such that a fourfold increase in the dose of 5-HT was necessary to produce the same reflex reduction in heart rate as occurred before administration of the antagonist (Fig. 3b). Thus, M-receptors are responsible for the initiation of this reflex by 5-HT and can be blocked by very low doses of ICS 205-930.

Inhibition of 5-HT-induced pain

5-HT causes pain when applied to a blister base on the human forearm and it markedly potentiates the vascular pain produced by bradykinin^{26,27}. Therefore, we investigated whether these actions are mediated by D- or M-receptors.

The M-receptor agonist 2-methyl-5-HT was as effective as 5-HT in inducing a pain response, whereas the D-receptor agonist *S*(+)- α -methyl-5-HT was ~100 times less potent (Fig. 4). Consistent with the pain-producing effects of 5-HT being mediated through M-receptor activation was the finding that the D-receptor antagonist methysergide did not inhibit 5-HT-induced pain, whereas ICS 205-930 at the low concentration of 10⁻⁸ M caused a marked rightward shift of the 5-HT pain dose-response curve. The inhibitory effect of ICS 205-930 could be

Fig. 3 The von Bezold-Jarisch effect in anaesthetized rats. *a*, Dose-response curves for 5-HT (●; *n* = 5) and 2-methyl-5-HT (○; *n* = 4). The selective D-agonist *S*(+)- α -methyl-5-HT was totally inactive up to a dose of 1,000 µg per kg, the highest one tested (*n* = 5, data not shown). *b*, Dose-response curves to 5-HT before (●; *n* = 5) and 5 min after the intravenous administration of the 5-HT D-receptor antagonist methysergide (○; 100 µg per kg; left panel; *n* = 4) or the M-receptor antagonist ICS 205-930 (□; 1 µg per kg; right panel; *n* = 5). Vertical bars indicate s.e.m. in each case. 'Area' refers to the area under the time-heart rate curve. **Methods.** Male rats weighing 220–270 g were anaesthetized by injecting urethane (1.25 g per kg) into the peritoneal cavity. Blood pressure and heart rate were recorded by standard techniques using a Statham transducer. Injections were made into the jugular vein. Rapid bolus injections of 5-HT (5–100 µg per kg) given at 5-min intervals elicited abrupt dose-related reductions in cardiac rate of short duration and reproducible magnitude. The area under the curve describing the reflex bradycardia (ordinates) quantified the effect.

Table 2 Antagonism of M-receptors in isolated tissues

Experiments to assess the affinities of three competitive M-receptor antagonists against 5-HT or 2-methyl-5-HT on the three isolated tissues were performed as described in Fig. 2 legend. The pA_2 and slope values were obtained by transforming the data from concentration-response curves to 5-HT or 2-methyl-5-HT conducted in the absence or presence of the respective antagonist from a minimum of three independent experiments, as described elsewhere³⁵. DR , dose ratio (the factor by which the agonist concentration has to be increased in the presence of the antagonist to obtain a response identical in magnitude to that recorded in the absence of the antagonist); B , antagonist concentration. If 5-HT and the antagonist under consideration compete for a common site, then $\log(DR-1) = \log(B) - \log K_B$, where K_B is the apparent dissociation constant for the antagonist-receptor interaction³⁶. In this case the regression of $\log(DR-1)$ on $\log(B)$ (Schild plot³⁵) yields a straight line of unity slope and a pA_2 value of $-\log K_B$. Slope and pA_2 values given here were obtained from linear regression analysis of the Schild plots. In all three tissues, compounds I, II and III behaved as true competitive antagonists, causing parallel rightward displacements of the agonist concentration-response curves without significantly reducing the maximum effect. In addition, the slope of $\log(DR-1)$ on $\log(B)$ was not significantly different from unity (*t*-test), showing that 5-HT and the antagonists compete for common receptor sites in these tissues.

Fig. 4 Painful effects of 5-HT and methylated analogues when applied to a blister base on the human forearm. *a*, Effects of 5-HT (●; $n=5$), 2-methyl-5-HT (○; $n=3$) and *S*(+)- α -methyl-5-HT (*; $n=3$) in causing pain. *b*, Concentration-response curves for 5-HT in the absence (●; $n=4$) or presence of 10^{-5} M methysergide (○; $n=3$; left panel) or 10^{-8} M ICS 205-930 (□; $n=4$; right panel). Antagonists were applied to the blister base for 20 min before applying 5-HT in their continued presence. Vertical bars indicate s.e.m. in each case.

Methods. Double-blind studies were conducted on five healthy male volunteers aged 32–55 yr. Blisters were produced on the medial aspect of the forearm as described previously²⁶. Increasing concentrations of 5-HT (10^{-8} – 10^{-5} M) were applied to the blister base in Krebs–Ringer solution. The contact time in each case was 2 min. Subjects were asked to register the pain experienced during each 2-min interval by moving a lever graduated on a 0–3 rating scale (0=no pain, 1=slight pain, 2=moderate pain, 3=severe pain) coupled to a linear integrator that then recorded the area under the 'pain intensity-time curve'. The concentration of 5-HT was increased every 2 min until one was reached where no further pain was produced. In this way, a cumulative dose-response curve for 5-HT could be constructed.

fully reversed on washing off the antagonist with buffer for 60 min.

To confirm that this effect of ICS 205-930 reflected a specific antagonism of 5-HT and not a general time-dependent reduction in the sensitivity of the blister base to all painful stimuli, dose-response curves for bradykinin (10^{-8} – 10^{-6} g ml⁻¹) were performed before, during and after incubation of the blister with ICS 205-930. The three dose-response curves were virtually superimposed and the maximum response similar at each time point (data not shown). Thus, in contrast to its effect on 5-HT responses, ICS 205-930 did not inhibit bradykinin-induced pain.

Concomitant with the pain response, 5-HT caused a wheal and flare reaction that presumably occurred as a result of the activation of sensory nerve endings in the skin and the consequent liberation of substance P by an axonal reflex mechanism²⁸. This was also inhibited by 10^{-8} M ICS 205-930. At the higher concentrations of 5-HT needed to induce pain in the presence of the antagonist, the wheal and flare response reappeared.

5-HT also caused a marked potentiation of bradykinin pain responses and this could be abolished by ICS 205-930 (Fig. 5). This inhibitory effect was partly reversed on washing off the antagonist for 20 min. Thus, ICS 205-930 not only inhibits pain responses to 5-HT in this system, but also blocks its ability to potentiate bradykinin responses.

These studies show that 5-HT induces its painful effect in humans through activation of neuronal M-receptors and that this can be selectively and reversibly inhibited by the M-receptor antagonist ICS 205-930.

Fig. 5 Potentiation of the painful effects of bradykinin on the human blister base by 5-HT and inhibition of this effect by ICS 205-930. Pain produced by a solution containing 10^{-8} g ml⁻¹ bradykinin alone (open columns) or in combination with 10^{-4} M 5-HT (hatched columns) was recorded before, during and after incubation of the blister base with 10^{-8} M ICS 205-930. Mean values obtained from five male volunteers are given. Vertical lines on each column indicate s.e.m.

Methods. Double-blind studies were performed in a further group of male volunteers aged 22–45 yr as described in Fig. 4 legend. In this series of experiments 10^{-8} g ml⁻¹ bradykinin was applied to the blister base first and the response recorded. This concentration of bradykinin produced a small pain response ('before', open column). It was subsequently washed off and the blister base incubated with buffer for 20 min before 10^{-4} M 5-HT was applied repeatedly. Initially this induced a large pain response as expected, but this subsided over the next 2–6 min despite repeated reapplication of the same 5-HT concentration. Subsequently 10^{-8} g ml⁻¹ bradykinin was applied to the blister in the continued presence of 10^{-4} M 5-HT for 2 min, resulting in a 10-fold increase in the bradykinin response ('before', hatched column). The bradykinin/5-HT combination was then washed off for 20 min with buffer, after which the blister base was incubated with 10^{-8} M ICS 205-930 for a further 20-min period. The responses to bradykinin (10^{-8} g ml⁻¹; 'during', open column) and the bradykinin/5-HT combination (10^{-8} g ml⁻¹ and 10^{-4} M, respectively; 'during', hatched column) were then recorded in the continued presence of 10^{-8} M ICS 205-930. ICS 205-930 completely inhibited the potentiation of bradykinin pain caused by 5-HT. This inhibitory effect of ICS 205-930 was partly reversed on washing off the antagonist for 20 min ('after').

Discussion

Compounds such as the ergot alkaloids, which possess the ability to inhibit the action of 5-HT at D-receptors on smooth muscle cells or at postsynaptic 5-HT₂ receptors in the central nervous system, have been available for many years²⁹. Here we describe the synthesis of highly potent and selective antagonists of another class of 5-HT receptors, M-receptors, located on peripheral nerves. Significant differences in the affinity constants obtained with the same competitive antagonist on different bioassay systems indicate that there are at least three distinct subclasses of these M-receptors.

During the course of this work we became aware of a similar project by J. Fozard and his colleagues. Based on earlier observations that (–) cocaine and structurally related compounds act as competitive antagonists at neuronal 5-HT receptors in the rabbit heart and guinea pig ileum^{8,10,11}, this group synthesized analogues with improved potency and selectivity, which yielded a series of compounds that are antagonists at 5-HT M-receptors in the heart³⁰. A report describing the pharmacological properties of one of these drugs, MDL 72222 (3,5-dichloroben-

zoilytropine ester), appeared during the preparation of this manuscript³¹. Unlike the indoletropanyl and homotropanyl esters synthesized by our group, none of these benzoyltropine analogues blocks 5-HT M-receptors in the guinea pig ileum or exhibits the remarkably high potency for vagal M-receptors achieved with many of our antagonists¹⁸. Indeed, some of the indole compounds we have synthesized are the most potent drugs of any pharmacological class so far described.

Studies in humans and rats with the selective antagonist ICS 205-930 show that M-receptors are present on sensory nerve endings in the skin and right ventricle of the heart. The ability

of M-receptor antagonists to block selectively the painful effects of 5-HT when applied to a blister base on the human forearm suggests that such compounds might present a novel approach to the management of conditions such as migraine and cluster headaches, where 5-HT may be involved in the genesis of vascular pain^{27,32}. This possibility has been discussed previously in detail²⁴ and encouraging preliminary clinical results with MDL 72222 support this contention³³.

We thank W. Bielser, R. Furler, P. Gugger and F. Luh for technical assistance and Dr K.-H. Buchheit for providing some of the data on the guinea pig ileum.

Bignami *et al.*¹ have reported evidence for an increasing 59-s period in the X-ray emission from the high-energy ($E \geq 50$ MeV) γ -ray source Geminga. Their claim is based on results of a search for periodicities at around 59s in the emission from the X-ray source 1EO630+178, which has been proposed as a possible counterpart of Geminga². We show here that the primitive indication by SAS-2 (ref. 3) of a 59-s periodicity in the γ -ray flux from Geminga is not statistically significant, and because it has also not been confirmed by COS-B (ref. 4), must be disregarded; the statistical significance of the results obtained from periodicity searches in the X-ray data is significantly lower than that reported by Bignami *et al.*¹. As a consequence, the identification of 1EO630+178 with the γ -ray source 2CG195+04 (Geminga) through a 59-s pulsation cannot be claimed.

The first suggestion of a possible 59-s periodicity in the Geminga γ -ray emission was derived from SAS-2 data³. The analysis was performed on a data set consisting of 121 photons, energy >35 MeV, detected over three separate observation intervals, each about 1 week long, with 37, 28 and 56 counts respectively. These data were searched for pulsation and the result was a 25-bin phase histogram with a χ^2 of 78 for a trial period of 59.0074s, increasing at a constant rate of 2.23×10^{-9} s per s. Without entering into the details of the analysis method used by Thompson *et al.*³, we can evaluate the chance occurrence probability of that result. For 121 counts uniformly spread over 25 bins the central limit theorem does not hold and the theoreti-

cal probability distribution of the χ^2 cannot be used. We derived the actual probability distribution by making a Monte-Carlo simulation of 10^6 sets of 121 counts uniformly distributed in three observation intervals as in the SAS-2 experimental conditions. The result is shown in Fig. 1. It is evident that $P(\chi^2 \geq 78) \approx 1 \times 10^{-6}$. Therefore, no more than 1,000 trials are allowed in order for the SAS-2 indication to be statistically significant. The number of trials used by the SAS-2 team was actually 8×10^4 around an input period of 58s (D. Thompson, personal communication), which implies a global chance occurrence probability of $\sim 8\%$ for the reported effect. Furthermore, as the choice of the input period was not derived from independent studies but from an investigation of the same γ -ray data, the implicit number of trials made to identify it should also be taken into account. Therefore, the value of 8% is a lower limit. On the other hand, Thompson *et al.*³ were aware of the weakness of their indication. After showing the effect they, in fact, declared that "... in view of the number of trials used ... the evidence for this periodicity is not statistically compelling but is worth examination by future experiments".

COS-B has observed the general direction of Geminga five times. Bignami *et al.*¹ refer to the results of a preliminary analysis of the first observation, made from 17 August to 17 September 1975, during which COS-B was pointing at the Crab pulsar and Geminga was visible at 15° off axis⁵. The quoted Caravane Collaboration paper stated a confirmation (1% chance occurrence probability) of the 59-s effect claimed by SAS-2. However, the χ^2 of the histogram, obtained after 133 trials was 43.6 and then, in our reevaluation, the global chance occurrence probability of the COS-B effect is $1.2 \times 10^{-3} \times 133 \approx 16\%$. Later, the COS-B team extended the analysis when the data from two more observations became available. Due to an increase in source counts by a factor of ~ 5 and more optimized selections, a much better signal-to-noise ratio than in the previous analysis became available. As a result, Masnou *et al.*⁴ concluded that "... no periodicity is observed around the 59s value". Note that the γ -ray flux of Geminga has remained constant within the statistical uncertainties from the SAS-2 (ref. 3) observations to those of COS-B (ref. 6). Therefore, applying the reasonable

Fig. 1 *a*, Theoretical probability distribution of the χ^2 with 24 d.f. *b*, Probability distribution of the variable $y = \sum(x_i - \bar{x})^2 / \bar{x}$ where $\bar{x} = 121/25$ and x_i is the content of the i th bin of the histogram obtained by folding, with a period of 59s, the arrival times of 121 events, uniformly distributed in three time intervals of 7, 5 and 7 days, respectively (total elapsed time between the beginning of the first week and the end of the third week is 131 days, as in the SAS-2 case).

Fig. 2 Distribution of the expected reduced χ^2 as a function of radius R (solid line) compared with reduced χ^2 values (*) obtained in ref. 1 by folding the IPC 10371 data with a period of 59.737s.

hypothesis that the shape of the light curve and the pulsed fraction of the flux has also remained stable, we expect a strong signal in the COS-B data due to the high counting statistics. In fact, the peak of the SAS-2 light curve when scaled to the COS-B exposure of Geminga would show up at the level of at least 16σ in the case of observation period 14 alone. Despite all the effort devoted by the Caravane Collaboration to detect periodicity effects in the Geminga data, no such result has been found.

The absence of a timing signature in the γ -ray emission from Geminga makes it impossible to identify a counterpart at other wavelengths. This also applies to the candidate-counterpart X-ray source 1E0630+178. Nevertheless, Bignami *et al.*¹ have centred the temporal analysis of the X-ray data of 1E0630+178 at the disclaimed Geminga period of 59s. The reported X-ray time analysis can also be criticized for several reasons:

(1) The chance occurrence probability of the 59-s effect in the Einstein 10371 data has been incorrectly calculated. As a result of the 20 trial periods scanned, a reduced χ^2 of 3.94 was obtained, corresponding to a global chance occurrence probability of $\sim 5 \times 10^{-5} \times 20 = 1 \times 10^{-3}$. Bignami *et al.*¹ quote a probability of 2×10^{-5} for the same data. This error is due to two reasons. First the single trial probability used to obtain a reduced χ^2 of 4.26 (9 d.f.) was 1.5×10^{-5} (ref. 7) and not 1×10^{-6} . Second, the value of 4.26, used instead of 3.94, is the result of fine scanning performed in addition to the initial 20 trials. Therefore, the appropriate number of periods searched is higher than 20, the value used by Bignami *et al.*¹. The same criticism applies to the combined data of IPC 10371 and HRI 8353, again an error in the single trial probability and the underestimated number of trials.

(2) Bignami *et al.*¹ fixed, *a priori*, the radius R (in pixels of 8 arc s) from the source position at $R = 23$ in their event selection and, correctly, discuss, *a posteriori*, whether the distribution of χ^2 values as a function of R behave as expected for a genuine source effect. This can be better judged from Fig. 2 which shows the reduced χ^2 expected for various values of R as derived from the relation $\text{reduced } \chi^2 = C \times NS^2 / NT + 1$ (ref. 8) (where NS is the number of source counts and NT is the total number of counts taken from Fig. 1 of ref. 1 and C is obtained by normalization at $R = 23$). Figure 2 shows that the χ^2 value at $R = 23$ is an upward fluctuation from the expected general trend. Therefore, the probability level of 1×10^{-3} is the lower limit to the probability that the reported effect is due to a random fluctuation.

(3) The useful observation time of the first Einstein observation (IPC 3333) is only 0.29 of that of the second and we expect a reduced χ^2 of 2.1 (chance occurrence probability of 50% in 20 trials). The measured value of 3.6 can only be reconciled with the IPC 10371 result and the SAS-2 indication, on which this search has been based, if three parameters are adjusted, namely the $\dot{P}$ value, the intensity of the pulsed emission from 1E0630+178, and possibly the shape of its light curve. Therefore, the effect found in the IPC 3333 data cannot be considered as independent evidence of a genuine effect, nor can the significances derived from the two observations be combined without taking into account the additional degrees of freedom.

Finally, we dispute the arguments based on the Zyskin and Mukanov results⁹ derived from measurements at ultra-high energies in 1979 and 1981. First, the result derived from the 1979 observations is declared by the authors to be statistically weak (6% chance occurrence probability). Second, for the 1981 data Zyskin and Mukanov show their 'light curve' with 19 bins and a χ^2 of 43.6. To obtain this effect as a random fluctuation, they use 10 d.f. in their probability calculation instead of 18. Using 18 d.f. the probability increases up to $6 \times 10^{-4} \times 100 = 6 \times 10^{-2}$ (compared with their quoted probability of 5×10^{-4}). Therefore, the result of the analysis of the 1981 data cannot be considered significant either. In addition, the obtained period is not consistent with the P and $\dot{P}$ derived from the Einstein or SAS-2 data and cannot be taken as independent evidence.

We conclude that the identification of Geminga with 1E0630+178 and the consequent speculations made by Bignami *et al.* are based on arguments too weak to be conclusive. The mystery of 2CG195+04 does not seem to be solved, although 1E0630+178 continues to be an interesting candidate counterpart.

Joint STARE and SABRE radar auroral observations of the high-latitude ionospheric convection pattern

M. D. Burrage*, J. A. Waldock*, T. B. Jones* & E. Nielsen†

* Department of Physics, Leicester University, University Road, Leicester LE1 7RH, UK

† Max-Planck-Institut für Aeronomie, 3411 Katlenburg-Lindau, FRG

The projection of the magnetospheric convection electric field into the ionosphere drives an asymmetric two-cell pattern of plasma circulation in the auroral zone. The Scandinavian Twin Auroral Radar Experiment (STARE) and the Sweden And Britain auroral Radar Experiment (SABRE) are two similar and independent coherent radar systems which can estimate *E*-region electron drift velocities at auroral latitudes. By combining their measurements, we have monitored simultaneously, for the first time, the convection flow pattern over 8 degrees of latitude. We show here how this allows a more extensive study of the nightside (Harang discontinuity) and dayside (cusp) boundaries between the cells, and enables spatial and temporal features of the flow pattern to be resolved.

The STARE and SABRE systems consist of two multi-beam radars that are sensitive to electrostatic ion-acoustic waves, which are produced in association with current flows in the auroral zone E-layer. The phase velocity of these irregularities is approximately equal to the electron drift velocity¹, and can be determined from the mean Doppler shift of the transmitted radar signal. Each radar measures the backscatter intensity and Doppler velocity of irregularities at each of 50 ranges within eight beams, providing a total common viewing area in the auroral E-region of ~200,000 km². The spatial resolution is ~20 × 20 km and the temporal resolution is usually 20 s. The Doppler shifts measured by the two radars are combined to give the electron drift velocity in a two-dimensional array of geographical locations within the viewing area. Recent EISCAT/STARE comparisons² indicate that the coherent auroral radar underestimates the higher flow speeds, although the directions are accurate. An empirical correction factor has been developed, the validity of which is yet to be established for SABRE. No correction has therefore been applied to the data presented here.

The STARE system³ has been operated by the Max-Planck-Institut für Aeronomie (MPI), Lindau, FRG, since 1977 and consists of radars at Malvik in Norway and Hankasalmi in Finland. SABRE⁴ was completed in 1982 and is operated jointly by Leicester University, UK and by MPI. The two SABRE radars are located at Wick in Scotland, and at Uppsala in Sweden.

In 1961, Axford and Hines⁵ proposed that viscous interaction between the solar wind and a closed magnetosphere would produce a high-latitude two-cell ionospheric convection pattern. At the same time, Dungey⁶ introduced the concept of solar wind interaction with an open magnetosphere through magnetic reconnection. This mechanism involves the merging of geomagnetic field lines on the dayside of the Earth's magnetopause with the interplanetary magnetic field (IMF). As the IMF is frozen into the solar wind, the opened field lines are 'dragged' across the poles, transporting plasma in an anti-sunward direction. The field lines reconnect in the magnetospheric tail and the return flow is on closed field lines around the flanks of the magnetosphere. It is generally accepted that both viscous interaction and magnetic reconnection processes drive plasma convection within the magnetosphere and that the ionospheric projection of these motions takes the form of a two-cell pattern (Fig. 1). Although the gross features of this pattern have now been well established, recent observations^{7,8} indicate that the shape and relative sizes of the convection cells are considerably modified by geomagnetic substorms and by the orientation of

Fig. 1 The two-cell convection pattern, plotted in invariant latitude against magnetic local time (MLT), for moderately disturbed geomagnetic conditions. Superimposed is the path taken by the combined STARE and SABRE viewing area, as the Earth rotates beneath the cell pattern.

Fig. 2 Simultaneous STARE and SABRE flow velocity observations made at 1111 UT 6 September 1982 in the Harang discontinuity region. The velocities are given as a function of latitude and longitude.

the IMF. From several days of STARE observations, it has been suggested⁹ that as magnetic activity increases: (1) the convection flow speeds increase; (2) the flow pattern expands; (3) the morning cell is enlarged with respect to the evening cell; and (4) the whole convection pattern rotates clockwise (in the Northern Hemisphere) towards earlier local times.

We now consider simultaneous STARE and SABRE observations of flows associated with both the morning and the evening convection reversals. An example of the convection flows measured in the vicinity of the evening reversal or Harang discontinuity is shown in Fig. 2 which indicates the convection flow vectors at 1111 UT 6 September 1982 in both viewing areas, with the SABRE field of view located to the south-west. The length and direction of each vector represent the flow speed and direction respectively. The flow direction in the STARE field of view is predominantly eastward, while that in the SABRE viewing area is westward. From an examination of the temporal development of the flow pattern, it was established that at this

Fig. 3 Combined STARE and SABRE convective flow velocity measurements for *a*, 6 September 1982, 1830–2000 UT; *b*, 7 August 1982, 0600–1200 UT. The velocities are given as a function of latitude and time, averaged over the longitude range 8–18° E.

time the viewing areas lie either side of the Harang discontinuity, with STARE and SABRE observing the morning and evening convection cells respectively. Figure 3*a* illustrates the convection flow velocities, as a function of latitude and time, averaged over the longitudinal interval 8–18° E. This is chosen to include both the eastern edge of the SABRE viewing area and the western edge of the STARE viewing area. Because of the longitudinal displacement between the two viewing areas, difficulties arise with this averaging process when the convection flow is not spatially uniform. The plot covers the period 1830–2000 UT, during which time the Harang discontinuity passed through both viewing areas. Figure 3*a* indicates the transition from the region of westward flow, which is associated with the evening convection cell, to that of eastward flow associated with the morning cell. The discontinuity moves equatorward with time throughout the entire latitude range, although the penetration speed of the eastward flow is latitudinally dependent. The equatorward drift is $\sim 250 \text{ m s}^{-1}$ within the STARE viewing region but has increased to $1,000 \text{ m s}^{-1}$ by the time the discontinuity passes through the SABRE viewing area. The sudden change at around 68° N arises from the longitudinal resolution limitation mentioned above, and indicates the presence of strong spatial velocity variations in the auroral E-region. Owing to the exceptionally high level of magnetic activity at this time ($K_p = 7$), the convection cell pattern has expanded equatorwards, and the strong auroral zone flows normally found at latitudes above 67° N are located within the latitude range covered by SABRE. The STARE radar measures weaker flows characteristic of the

polar cap region. In quiet geomagnetic conditions, the Harang discontinuity would be expected to occur at 2300 UT (refs 7, 9). This particular reversal took place between 1850 and 1940 UT, implying a clockwise rotation of the entire cell pattern by $\sim 3\text{--}4 \text{ h}$. Despite the magnetically-active conditions, the gross features of the observed flows are in good agreement between the two systems, demonstrating that STARE and SABRE may be usefully combined for increased latitudinal coverage in the morphological study of convection flows in the auroral ionosphere.

Although the Harang discontinuity is frequently observed by STARE and SABRE, convection flows associated with the morning reversal are very weak at these latitudes. In highly disturbed conditions, however, strong flows can occur in this region at latitudes below 64° N (refs 8, 10). Figure 3*b* is an example of a morning sector observation, illustrating the temporal development of the plasma flow pattern in the vicinity of the convection reversal, for the time interval 0600–1200 UT 7 August 1982. The value of K_p was +7 during the period 0600–0900 UT and –7 between 0900 and 1200 UT. In contrast to the evening sector example, the change in flow direction is from eastwards to westwards, and the flow pattern displays a throat-like structure which widens with decreasing latitude. Although auroral radar observations of the morning reversal are rare, they are of particular interest because in this local time sector the Earth's field lines map directly into the outer magnetosphere. Measurements made in this region of the high-latitude ionosphere can, therefore, be used to infer the properties of the plasma in the polar cusp, which is the highly dynamic zone of direct interaction

between the Earth and the interplanetary environment. Future studies involving the correlation of STARE and SABRE cusp flow observations with the behaviour of the IMF will enhance our understanding of the field line reconnection mechanism by which the solar wind drives the high-latitude convection cell pattern.

The STARE radar was constructed and is operated by MPI, Lindau, FRG. SABRE was constructed and is operated jointly by MPI and the Department of Physics, Leicester University, UK.

Increasing abundance of CBrClF₂ in the atmosphere

S. Lal, R. Borchers, P. Fabian & B. C. Krüger

Max-Planck-Institut für Aeronomie (MPAE),
D-3411 Katlenburg-Lindau, FRG

The importance of bromine chemistry was recognized shortly after Molina and Rowland¹ had drawn attention to chlorine atom-catalysed destruction of ozone. Bromine atoms are even more efficient catalysts than chlorine^{2,3}, and both may act synergistically to deplete ozone in the lower stratosphere⁴. Some measurements of bromine-containing source gases, such as CH₃Br, CHBr₃, CH₂BrCH₂Br, CH₂Br₂, CBrF₃ and CBrClF₂ have been reported for the troposphere⁵⁻⁸, their vertical distribution in the stratosphere is unknown except for CBrF₃ (CFC-13B1) and CH₃Br (ref. 6). These, together with the fully halogenated CBrClF₂ (CFC-12B1), are probably the most important source gases for stratospheric bromine radicals. We report here the first stratospheric profiles of CBrClF₂, up to 25 km, measured at 44° N during three consecutive years. From these data it follows that the atmospheric abundance of this halocarbon is growing rapidly, at a rate of 20% per year in the Northern Hemisphere, corresponding to a worldwide emission of $\sim 3.6 \times 10^3$ tons per year.

Like CFC-13B1, whose vertical distribution has already been measured⁶, CFC-12B1 has an anthropogenic origin: both substances are used as fire extinguishers. Their ultraviolet absorption characteristics are similar to those of the corresponding chlorine-containing species, but shifted towards longer wavelengths. Thus halogen atoms are released from these molecules in the lower stratosphere, leading to overall atmospheric lifetimes of 29-42 yr and 62-117 yr for CFC-12B1 and CFC-13B1, respectively⁹. Both substances are abundant at ~ 1 p.p.t.v. (parts per 10^{12} by volume)^{5,8,10}. Compared with CH₃Br, the main natural bromine-containing halocarbon whose tropospheric mixing ratios were found to lie between 5 and 20 p.p.t.v. (refs 5, 8, 10), the anthropogenic CFC-12B1 and CFC-13B1 contribute between 10 and 30% to the present organically-bound bromine.

Stratospheric profiles of CBrClF₂ were obtained by analysing air samples collected cryogenically by means of neon-cooled samplers. The new MPAE samplers¹¹ allow the collection of samples of 30 litres STP (standard temperature and pressure) at 15 different altitudes up to 40 km. CBrClF₂, among other halocarbons, was analysed by gas chromatography with an electron capture (EC) detector. A 3 m $\times$ 2 mm internal diameter (i.d.) glass column packed with OV-101 on Chromosorb WHP

Fig. 1 The vertical distribution of CBrClF₂ (CFC-12B1) measured at 44°N during three consecutive years. The theoretical profile was computed by means of a time-dependent one-dimensional model, for 20 September 1982.

80-100 mesh was used for separation, with temperatures varying between -50 and +60 °C and argon/methane (10%) as the carrier gas¹². In combination with a cryotrap preconcentrator, CFC-12B1 is analysed with a precision of $\pm 5\%$, the detection limit being 0.03 p.p.t.v. The absolute calibration is achieved by two-step static dilution with $\sim \pm 10\%$ accuracy.

Results from three balloon flights carried out over southern France, on 20 September 1982, 10 September 1983, and 1 October 1984, are presented in Fig. 1. Most samples were collected with a copperwool filter attached to the air intake, to destroy incoming ozone¹³. Sampling tests performed in simulated stratospheric conditions, with gas mixtures containing 5 p.p.t.v. of CFC-12B1, gave no indication of sampling errors exceeding the analytical precision ranges of $\pm 5\%$. In contrast to some other halocarbons, CFC-12B1 does not change in the sampler when ozone is added; thus no systematic differences occur between samples collected with or without this filter. All analyses were completed within 2 months after each flight.

By repetitive analyses and cross-checks, it was found that the sensitivity of the analytical system had changed in 1984. Thus, a correction factor of (1.14 ± 0.04) had to be applied to the 1982 and 1983 profiles. No change of sensitivity was found between 1982 and 1983. The step-like structures observed in the profiles shown in Fig. 1 reflect real variations which were also observed in the profiles of other source gases analysed together with CFC-12B1. Such structures were found to be due to large-scale advection processes^{14,15}.

If the lowest two samples of each flight are considered to be representative of high-tropospheric conditions (in fact, the tropopause was between 11 and 12 km for all three flights), the abundance of CFC-12B1 increased from 1.03 p.p.t.v. measured on 20 September 1982, to 1.31 p.p.t.v. on 10 September 1983, and to 1.49 p.p.t.v. on 1 October 1984. These values correspond to relative growth rates of 28% per year for 1983 and 12% per year for 1984, or 20% per year averaged over both years. If the worldwide emission pattern of CFC-12B1 follows that of other anthropogenic substances, it is reasonable to assume that $>90\%$ of the emission occurs in the Northern Hemisphere. If no hemispheric mixing were to occur, the increase of the abundance of CFC-12B1 observed at northern midlatitudes would correspond to a global annual release rate of 2.6×10^3 tons per year

However, as interhemispheric mixing occurs with a time constant of ~ 2 yr, the global release rate is likely to amount to $\sim 3.6 \times 10^3$ tons per year. Considering the error of $\pm 4\%$ related to the sensitivity correction of our analytical system, the range of this value may be $\pm 8\%$.

No values for the global production and emission rates of CFC-12B1 are available. For model studies, we have adopted an (arbitrary) scenario of exponential growth with global emission rates doubling every 18 yr. Scaling of these emission rates was performed such that the modelled profile, computed with a time-dependent one-dimensional model for 20 September 1982, matched the lower part of the observed profile (Fig. 1). Annual emission rates obtained in this way increased from ~ 1 kton per year in 1955 to 3.07, 3.23 and 3.34 kton per year for 1980, 1981 and 1982, respectively. Although the average annual emission rate of 3.6 kton per year derived from our measurements, for the 1983–84 period, seems to be consistent with this adopted emission scenario, the large relative increase of 20% per year observed for CFC-12B1 indicates that the doubling time of the annual worldwide emission rates is likely to be much shorter than 18 yr. The rapid growth of the atmospheric abundance of CFC-12B1 is also confirmed by near-surface measurements. While Rasmussen *et al.*⁸ report a value of 1.1 ± 0.2 p.p.t.v. measured at Barrow (Alaska) during 1983, a sample of fresh polar air collected on 5 February 1985 close to the MPAE site, yielded 2 p.p.t.v. of CFC-12B1. The abundances of CFC-11, CFC-12, CH_2Cl_2 and CCl_4 , which were analysed together with CFC-12B1, gave no evidence of local or regional pollution of this sample.

In the stratosphere, CFC-12B1 mixing ratios decrease by two orders of magnitude, to $\sim 10^{-14}$ at 25 km. The profile computed with the time-dependent model shows a slower fall-off with height, which reflects a well-known modelling problem related to source gases¹². Note that the rapid annual increase of CFC-

12B1 abundance is confined to heights below 20 km. In all three cases, radiosonde measurements from nearby meteorological stations revealed temperatures beginning to rise with height above 20 km. As stratospheric measurements of CO_2 indicate, substances from anthropogenic sources found above 20 km, in the height region of positive temperature gradient, have mostly penetrated through tropical upwelling, while the height region below 20 km is mostly governed by diffusion¹⁶. The related time lag for the 20–30-km layer with respect to the troposphere was found to be ~ 5 yr (ref. 15). This would confirm that the worldwide emission of CFC-12B1 into the atmosphere has been high in recent years.

Our source gas research programme has been sponsored in part by the German Federal Ministry of Research and Technology through grant KBF-MT 0450-0704563 2 and by the Deutsche Forschungsgemeinschaft through grant Fa 62-8/3. We thank the balloon launching team of the French CNES for the excellence of the launches.

Transient electro-optic Raman scattering in liquid crystals

H. J. Coles & J. Tipping

The Liquid Crystal Group, Schuster Laboratory,
University of Manchester, Manchester M13 9PL, UK

We report here the first realization of time-resolved electro-optic Raman scattering in a liquid medium. Using the characteristic signal from a Raman active band, we show that an applied pulsed electric field induces a macroscopic particle reorientation which may be followed by the transient changes induced in the Raman signal. We have chosen a liquid-crystal material as the medium because this allows us to compare the static and dynamic response with other conventional techniques. This comparison indicates the foundation of a new method for characterizing orientational processes, and the dynamics thereof, at the local molecular structure level. The method does not require the use of perturbing dye or spin probes.

Many molecules and particles have anisotropic electric, magnetic and optical properties. Particles in fluid suspension, for example, seem to be optically isotropic because of the randomness of their individual orientation until an external field is applied. Such a field (which may be electric, magnetic, acoustic or optical) induces a partial alignment of the particles and the bulk material becomes optically anisotropic. Thus, because of the field-induced orientation, the bulk properties reflect the anisotropic properties of the individual particles. For such suspensions, electric-field induced changes in the optical properties (that is, scattered intensity¹, birefringence², dichroism², optical activity³ and fluorescence⁴) have led to the establishment of a series of standard techniques of 'electro-optic' characterization.

The use of pulsed fields, particularly, has allowed bulk molecular reorientation to be studied in these systems.

Liquid-crystal systems are, however, more complicated⁵. Structurally they have anisotropic electric, magnetic and optical properties but, because they are highly condensed systems, particle interactions and associations cause local domain structure on the size scale of a few micrometres. Unless suitably aligned, these domains are randomly orientated in space and cause an intense scattering of light giving rise to a milky or turbid appearance. If, however, these materials are contained in a thin cell and surface alignment techniques⁶ are used, they become optically clear and electro-optic phenomena may be observed. Such cells used with low molecular weight organic compounds and suitable optical arrangements form the basis of the liquid-crystal display industry⁷. Because of the condensed nature of the materials, only bulk properties are normally able to be studied and experimental data are referred to a 'director' which is essentially the mean direction or orientation within a domain. An applied electric field will cause director reorientation which will relax back to its original state on removal of the field. Unlike the simple non-interacting particle case, the orientation and relaxation processes now become dependent on the applied voltage, the elastic forces in the medium, as well as the dielectric properties. The situation is complicated because the molecules may not be rigid and, thus, intra-molecular relaxation could occur. Hitherto, the optical dynamics have been limited to relating the director motion to bulk material properties. Using the inherent chemical specificity of the Raman effect which arises from the vibrational modes of the polarizability ellipsoid associated with particular bonds, we can show that transient electro-optic methods may be used to follow the reorientation of the Raman tensor associated with a particular bond in the system.

We have assembled a novel Raman microprobe apparatus (see Fig. 1), based on an argon-ion laser used in the continuous

Fig. 1 A schematic diagram showing the Raman experimental arrangement.

wave mode at a wavelength, λ , 488 nm. To avoid spurious heating effects in the samples, the output power was kept below 20 mW. The output beam was then optically filtered to remove laser plasma lines and guided to the cell-microprobe assembly. This assembly used infinity-corrected microscope objectives ($\times 50$ magnification) and was custom built to include glan-laser polarizers (for controlling the polarization plane of the input and scattered light) and spatial filtering (to ensure that only the scattering from the sample volume was detected). The sample holder was an electrically heated constant-temperature oven stable to at least $\pm 0.1^\circ\text{C}$ and capable of holding microscope slides with X-Y translation. The scattered light was then collected in transmission (that is at zero scattering angle) using a further microscope objective ($\times 50$ again) and steered (using prisms and lenses to adjust the input light to the correct numerical aperture) to a Spex 1402 double-grating spectrometer ($f = 7.8$). Light from this spectrometer, which used high-resolution holographic gratings (1,200 grooves per mm), was then detected using a high-gain cooled photon-counting photomultiplier tube. The output signal from the photomultiplier was recorded using a 72-channel digital correlator operating in the signal-averaging mode.

The sample chosen for study was pentyl cyanobiphenyl (5CB), a highly stable liquid crystal exhibiting a nematic phase at room temperature, held in a cell constructed from two conducting glass slides. The cell surfaces were treated with a polyvinyl alcohol film which was then rubbed to give planar alignment⁷. In this way the director was aligned in a controlled manner in the cell and its direction, in the plane of the glass slides, aligned parallel to the input polarization of the argon-ion laser beam. The plane of the transparent glass electrodes was perpendicular to this beam. A voltage applied across the electrodes, therefore, produced a field in the direction of propagation of the beam. When the cell was inserted into the microprobe assembly, an area of $\sim 5 \mu\text{m}^2$ was illuminated. This was viewed using a video camera and monitor adapted to the collection optics. The video system allowed the condition of the sample to be examined at any time and thus allowed us to verify that any changes in the optical properties recorded were not due to heating or damage to the sample. The sample thickness (and optical path length) was $30 \mu\text{m}$ and a.c. voltages of between 2 and $6 V_{rms}$ were applied to the sample. For all the measurements reported here, the voltage was applied either continuously (for the steady-state response) or in 300–800 ms pulses (for the transient measurements).

With the director aligned in the polarization direction of the input light, the Raman active bands studied here gave a maximum response (see Fig. 2a). On application of an a.c.

Fig. 2 Raman spectra for 5CB with: *a*, no applied field; *b*, an applied a.c. voltage of $2.2 V_{rms}$ at 500 Hz. Sample cell thickness was $30 \mu\text{m}$ and the polarization direction of both the input argon-ion laser beam and analyser for the scattered light was parallel to the director of the nematic phase. Temperature, 25.0°C . Numbers adjacent to the Raman lines correspond to the Raman shift from the exciting line at $\lambda = 488.0 \text{ nm}$. Assignments as follows: $1,179 \text{ cm}^{-1}$, C-H aromatic deformation; $1,285 \text{ cm}^{-1}$, C-C biphenyl link stretch mode; $1,607 \text{ cm}^{-1}$, C-C benzene ring stretch mode; $2,224 \text{ cm}^{-1}$, C $\equiv$ N cyano stretch mode. Increasing response at lower wavelengths marks the start of the wing of the Rayleigh scattering.

voltage across the cell, the liquid-crystal molecules orient according to their dipolar structure into the direction of propagation of the laser beam. The Raman tensors, therefore, rotate away from the polarization direction of the beam and the intensity of the Raman signal decreases (Fig. 2b). The strength of the Raman signals, with the steady-state field on, drop to about one-fifth of their field-off values. This reflects the high induced order in the system. On removal of the field, the spectrum relaxes back to its original field-off form. For both the field-on and field-off cases we have verified optically that the samples were not degraded.

Application of pulsed a.c. fields and the high sensitivity of the microprobe technique have allowed us to study time-dependent electro-optic Raman signals in these systems for the first time. A typical transient signal is shown in Fig. 3 for the $1,179 \text{ cm}^{-1}$ line. This response was recorded by monitoring the intensity (photon counts s^{-1}) at a fixed wavelength 517.8 nm (corresponding to this $1,179 \text{ cm}^{-1}$ line) as a function of time. From Fig. 3 it is clear that the field-on response time ($\sim 110 \text{ ms}$) is faster than the field-free decay ($\sim 400 \text{ ms}$). This is typical of such a liquid-crystal sample. In a normal liquid-crystal cell, the reorientational response time (τ_{on}) is a function of the applied voltage (V). For a planar-planar configuration, as used here, it would be expected, to a good approximation, that $\tau_{on} \propto V^{-2}$. We have measured τ_{on} as a function of V , Fig. 4, from which it can be seen that τ_{on} is indeed proportional to V^{-2} . Further, the field relaxation time (τ_{off}) should be independent of V . At

Fig. 3 Transient electro-optic Raman scattering in 5CB. Recorded signal corresponds to the $1,179\text{ cm}^{-1}$ Raman line. A and B denote the start and finish of the AC voltage pulse of amplitude $3.06 V_{rms}$ and frequency 500 Hz. Cell thickness was $30\text{ }\mu\text{m}$; temperature 25.0°C . The polarization conditions were as in Fig. 1.

Fig. 4 Transient electro-optic response time (τ_{on}) as a function of the applied root mean square voltage (V_{rms}) and its inverse squared (V_{rms}^{-2}). Experimental conditions as in Figs 1 and 2 with the exception of the varied applied voltage. Transient response time is defined as the time for the Raman signal to fall to $1/e$ of the difference between the field-off and field-on saturation values.

constant temperature, τ_{off} was observed to be independent of V . Therefore, we concluded that the transient electro-optic Raman scattering (TEORS) is monitoring orientational motion and relaxation phenomena. The data presented refer to the weaker $1,179\text{ cm}^{-1}$ line which corresponds to a C-H 'deformation' mode in the aromatic ring structure of 5CB. Stronger signals were recorded for the other lines, particularly the $1,607\text{ cm}^{-1}$ C-C 'stretching' mode. However, we have chosen to use the weaker band to illustrate the potential of the TEORS method. All of the bands studied exhibited the same τ_{on} and τ_{off} characteristics. This is expected because these bands are all associated with chemical bonds located in the rigid core structure of the cyanobiphenyl molecule. Although we are now carrying out a detailed analysis of both the τ_{on} and τ_{off} data and applying the method to more flexible molecules, it is evident that the response times reported are typical for such liquid-crystal materials. We have verified this by studying the electro-optic response times

of the unshifted Rayleigh line using crossed polars in the same switching conditions.

We have established a new electro-optic method for characterizing orientational motion in fluid systems using the chemical selectivity of the Raman effect. Because of this selectivity, we do not need to use solvated dye or spin probes to study the orientational processes. If this field-driven technique is combined with the linewidth⁸ and order parameter⁹ methods already established for Raman scattering, then in one apparatus one has all of the experimental features normally only available to methods such as NMR. There are further advantages in that the experiment is much less expensive and allows rapid time dependent phenomena to be studied in real time. The sample volume is small ($\sim\mu\text{m}^3$) and, therefore, any feature that may be observed using a normal optical microscope may be studied in the Raman apparatus. Note that low concentrations of micrometre-sized pollutants have been studied by a time-averaged Raman microprobe system¹⁰. These experiments may now be carried out as a function of time.

We have recently applied our time dependent method to dilute solutions of polymers and polymeric liquid crystals and these results will be reported soon. We also envisage extending the studies to two areas of interest in the field of liquid crystals. The first is in the study of dye-liquid-crystal interactions in the so-called guest-host effect¹¹ where the dye molecules clearly perturb the local molecular dynamics, and the second is in the study of biological liquid crystals. Our original experiment was set up with the intention of studying the motion of proteins in lipid bilayers and cell walls so that the influence of drug additives on the protein dynamics might be monitored. Now that the technique has been established, both of these studies will be carried out and hopefully lead to a better understanding of the importance of local dynamics in such complex condensed systems.

We thank the SERC for an equipment grant to H.J.C. and a research studentship for J.T.

Dependence of the flexural rigidity of the continental lithosphere on rheology and temperature

Nick Kusznir* & Garry Karnert†

* Department of Geology, University of Keele, Keele, Staffordshire ST5 5BG, UK

† Department of Geological Sciences, University of Durham, Durham DH1 3LE, UK

While the first-order mechanical properties of oceanic and continental lithosphere are well defined and explain the observed increase in lithospheric flexural strength with thermal age, the temporal variation of continental flexural rigidity following loading, and its dependence on lithospheric composition and temperature structure, is only just beginning to be appreciated. We describe here the results of a quantitative rheological model in which laboratory-determined rock deformation data and transient

Fig. 1 Horizontal flexural stress plotted against depth: *a*, as a function of time elapsed since loading for lithosphere with a thermal age of 300 Myr; rapid stress relaxation is associated with a corresponding decrease in flexural rigidity; *b*, as a function of thermal age at time 100 Myr since loading. Increasing the thermal age allows the flexural stresses to be supported to a greater depth. In particular, Palaeozoic (300 Myr) and Proterozoic (1,000 Myr) lithospheres are associated with high flexural rigidities for Cenozoic (30 Myr) and Mesozoic (100 Myr) loading respectively.

temperature distributions, resulting from intra-plate basin formation within continental interiors, have been integrated. Continental flexural rigidity is shown to be controlled by crustal thickness, lithospheric thickness through the temperature structure, and the interaction of these factors during basin formation. For thermally young lithosphere, the flexural rigidity is dominated by the quartzofeldspathic rheology of the crust, while for the thermally older lithosphere, it is dominated by the olivine rheology of the mantle. Flexural data, through thermo-mechanical models of lithospheric deformation, provide a powerful constraint on both the transient and steady-state temperature structure of the lithosphere.

Studies of geological loading within the oceans and continents have established that lithospheric flexure is an important mechanism by which emplaced loads are supported¹⁻¹³. The flexural properties of the lithosphere can be parameterized by the flexural rigidity, D , which relates to the effective elastic thickness, T_e , by $D = ET_e^3/12(1-\nu^2)$, where E is Young's modulus and ν is Poisson's ratio. Geologically, T_e is the depth to the critical lithospheric isotherm which defines the elastic-plastic transition^{1,5}.

Two fundamentally different quantitative models have been developed to investigate the temporal mechanical properties of the continental lithosphere—the elastic and Maxwell visco-

elastic models—which predict fundamentally different time behaviours of the lithosphere following loading^{6,13}. The elastic model, as modified to reflect the thermal structure of the lithosphere at the time of loading (that is, the thermo-elastic model¹⁰⁻¹²), predicts deflections which are dependent only on the thermal age of lithosphere at the time of loading. In contrast, the Maxwell visco-elastic model is characterized by an initial high flexural rigidity which decreases with time following loading such that only the time since loading is important in defining the flexural response⁶. Flexural stresses created in a Maxwell visco-elastic lithosphere relax asymptotically to zero over geological time. As a consequence of their different time behaviour, the two models predict significantly different basin geometries and stratigraphies^{5,7,9,13}.

While the flexural deformation within the oceanic and continental lithospheres can be successfully analysed using the elastic model, unacceptably high elastic bending stresses² (10–50 kbar), rheological considerations of the way in which rock-forming minerals deform¹⁴, and the failure to predict the observed rapid relaxation from the seismic to an asymptotic elastic thickness¹, invalidates a purely elastic response of the lithosphere to loading. Alternatively, the Maxwell visco-elastic model in which low lithospheric rigidities are predicted 100–

Table 1 Age, load and rigidity parameters of various geological features

Geological feature	Age of load (Myr)	Thermal age of basement (Myr)	Thermal age of basement at time of loading (Myr)	Effective rigidity ($\nu = 0.25$, $E = 10^{12}$ dyn cm ⁻²)	Symbol in fig. 3
Lake Agassiz	0.007–0.014	1,600–1,800	1,600–1,800	5.9×10^{31} – 1.3×10^{32}	1 (ref. 6)
Lake Algonquin	0.00115–0.00125	1,200–1,500	1,200–1,500	2.9×10^{31} – 1.1×10^{32}	2 (ref. 6)
Ganges Basin	2–50	750–1,600	700–1,558	5×10^{31} – 10^{32}	3 (ref. 13)
Appalachian Basin	280–450	900–1,100	450–820	5×10^{31} – 2×10^{32}	4 (ref. 13)
Lake Bonneville	0.015–0.02	24–290	24–290	2.4×10^{29} – 2.9×10^{30}	5 (ref. 6)
Molasse Basin	2–40	270–365	230–363	10^{30} – 10^{31}	6 (ref. 13)
Anadarko Basin	230–330	510–530	180–300	4.1×10^{30} – 1.9×10^{31}	7 (refs 35, 36)
Michigan Basin	280–450	500–800	50–520	4.9×10^{30} – 1.2×10^{31}	8 (ref. 12)
Gulf Coast Basin	2–120	170–190	50–188	1.5×10^{30}	9 (refs 37, 38)
Williston Basin	113–351	500–600	149–487	7.2×10^{30} – 4.0×10^{31}	10 (ref. 31)

200 Myr after loading^{4,6} is equally inapplicable¹². A generalized model of continental lithospheric flexure is needed, therefore, which combines the long-term asymptotic finite rigidity of the thermo-elastic model with the short-term rapid relaxation of the Maxwell visco-elastic model. Such a model, using laboratory-derived creep deformation properties of quartz, feldspars and olivines, is termed a thermo-rheological model and incorporates the temperature and stress dependency of lithospheric material. This model has been used to examine quantitatively the relaxation of flexure-induced stresses with time as a function of depth, geothermal gradient (or lithospheric temperature structure) and crustal thickness within the continental lithosphere. The calculated stress-depth relationships are then used to determine the effective elastic thickness, T_e , and flexural rigidity of the lithosphere as a function of time, since loading.

Purely elastic initial horizontal flexural stress is assumed to take the form of $\sigma_x(t=0) = \sigma_0(1 - 2z/L)$ where z is depth, L the initial lithospheric thickness and σ_0 the maximum flexural stress before failure. The model assumes a visco-elastic Maxwell rheology for each infinitesimal component of the lithosphere, that is, for each component, $e_x = \sigma_x/E - v\sigma_y/E - v\sigma_z/E + e_x^v$ and similarly for e_y and e_z , where e_x is total strain, σ is stress and e_x^v is the viscous creep strain.

Conservation of horizontal force before and after flexure allows the additional constraint,

$$\int_0^L \sigma_x dz = 0$$

By assuming that the infinitesimal layers comprising the lithosphere are welded together during stress relaxation implies that

$$\frac{de_x}{dz} = 0$$

Manipulation of the above equation with the additional constraints of $\sigma_z = 0$ and $e_y = 0$ (plane strain) gives

$$\sigma_x = \int_0^t \left(\frac{1}{L} \int_0^L k \dot{e}_v dz - k \dot{e}_v \right) dt'$$

where $k = E/(1 - v^2)$ and

$$\dot{e}_v = (\sigma_x(2 - v) - \sigma_y(1 - 2v))/6\eta$$

where η is the apparent viscosity. The derivation is described in greater detail in ref. 15.

Temperature and power-law stress-dependent ductile deformation is assumed to be controlled by dislocation and Dorn law creep of olivine in the mantle¹⁶⁻¹⁸, while crustal creep is modelled as the dislocation creep of dry (lower crust) and wet (upper crust) quartz¹⁹. Dislocation creep takes the mathematical form $\dot{e}_v = A \exp(-E/RT) \tau^n$ where τ is shear stress, T is temperature (K) and A , E and n are material constants. The upper crust is assumed to contain 50% quartz and the lower crust only 10% quartz.

Stress modification by near-surface brittle failure of the crust has not been included in the model so that the primary thermo-rheological effects controlling flexure can be clearly demonstrated. Upper lithospheric brittle failure, when included in the model, results in only a minor reduction in flexural rigidity. Rigidity, therefore, as calculated here, represents an upper bound.

The lithospheric geothermal gradient has a critical role in controlling the strength of the lithosphere because of the temperature-dependent rheology of the crust and mantle. To span the range of acceptable geothermal models, geotherms have been calculated using cooling plate models²⁰⁻²⁵ with plate thicknesses of 125 and 225 km. Radiogenic heat productivity distributions given by Sclater *et al.*²³ and Nicolaysen *et al.*²⁴ have been included in the 125- and 225-km models respectively. An initial uniform plate temperature of 1,333 °C is assumed²⁵. With time, the lithosphere cools progressively by conduction so that the lithospheric temperature structure is directly related to its thermal age^{12,26}.

Fig. 2 The flexural rigidity, D : a, plotted against time since loading for lithosphere of various thermal ages with quartz rheology crust and olivine rheology mantle; the rate of relaxation towards the asymptotic rigidity increases with decreasing thermal age of the lithosphere; b, plotted against linear time; the rapid relaxation period, regardless of thermal age, is <0.2 Myr; c, compared with an all-olivine rheology lithosphere; the increase in the olivine component accelerates the flexural rigidity stabilization; d, compared with a model in which the geothermal gradient has remained constant since loading. This (secondary) effect is to reduce the value of the asymptotic rigidity. Lithospheric cooling therefore, leads to a more rapid stabilization of flexural rigidity by 'locking in' flexural stresses.

Figure 1a shows horizontal flexural stresses at various times after loading for lithosphere with a thermal age of 300 Myr (equivalent to Hercynian-aged lithosphere) and crustal thickness of 35 km. The initial flexural stress has a maximum compressive value of -1 kbar at the surface ($\sigma_0 = -1$ kbar). With time, ductile deformation results in stress relaxation within the lower lithosphere, reducing the depth extent over which the stresses are supported. Figure 1b shows the horizontal stress remaining after 100 Myr since loading for a range of lithospheric thermal ages. The older, hence colder, lithosphere shows stress supported to increasingly greater depths, corresponding to greater effective elastic thicknesses. Rheological variations associated with the Moho and at mid-crustal levels can be seen to generate discontinuities within the stress-depth relationships. The model described above conserves plate curvature during stress relaxation. An alternative condition in modelling flexure, more applicable to the lithospheric response to superimposed loads, would be the conservation of bending moment. For such a condition, stress relaxation in the lower lithosphere is accompanied by stress amplification in the upper lithosphere in order for the lithosphere to support the load. While the two models predict different stress levels, the resultant flexural rigidities are expected to be similar.

Rather than tracking lithospheric stress, it is advantageous to measure the variation in lithospheric flexural rigidity as it is this parameter which characterizes the surface deformation of the lithosphere. A simple estimate of flexural rigidity is obtained from the depth to the neutral fibre. In Fig. 2a, flexural rigidity is plotted against the logarithm of time since loading for lithospheric models with various thermal ages. An inverse relationship exists between flexural rigidity and the time since loading, whereas it increases with increasing lithospheric thermal age.

Fig. 3 Modelled flexural rigidity predicted by the 225-km plate thermo-rheological model as a function of the thermal age of the lithosphere at the time of loading: *a*, for elapsed times 10^4 , 10^6 and 10^8 yr after loading; *b*, showing the effects of crustal thickness variation; the predictions of the thermo-rheological model are compared with those of the thermo-elastic model for the 300 °C and 600 °C isotherms; *c*, compared with the predictions of the 125-km plate model; curves for stretching by $\beta = 2$ and $\beta = \infty$ (the oceanic plate cooling model) are shown, *d-f*, as for *a-c* but with superimposed observations of continental flexural rigidities as a function of the lithospheric thermal age at the time of loading.

For thermally young lithosphere, flexural rigidity rapidly stabilizes (within 10^6 yr) after loading, while thermally older and colder lithosphere takes longer. Lithosphere of 1,000 Myr thermal age exhibits a slow but continuous decrease in flexural rigidity with time. The plots of Fig. 2*a* using a logarithmic time axis are, however, misleading with respect to the rate of the initial relaxation phase. Figure 2*b* shows the time since loading plotted linearly against flexural rigidity and indicates that the rapid relaxation of flexural rigidity actually occurs within the first 0.2 Myr following loading, after which it slowly approaches its asymptotic value.

Comparison of the post-loading behaviour of the lithospheric rheological models with both composite quartz-olivine (crust-mantle) and all olivine compositions (Fig. 2*c*) indicates that an olivine lithosphere approaches its asymptotic flexural rigidity significantly more rapidly than a quartz-olivine lithosphere. This suggests that oceanic flexural rigidity should stabilize more rapidly than that of the continental lithosphere and, therefore, that it is flexurally stronger than continental lithosphere of the same thermal age.

A contribution to the stabilization of flexural rigidity arises from the continued cooling of the lithosphere following loading. Its significance is summarized in Fig. 2*d* which shows that the rate of rigidity stabilization is increased for oceanic lithosphere and thermally young continental lithosphere, both of which cool rapidly (it is this rapid cooling which essentially 'freezes in' the effective elastic thickness²⁷). However, this freezing is, in effect, of secondary importance relative to the main controlling factor on flexural rigidity stabilization, which is the stress decay within a material characterized by a temperature- and stress-dependent power-law rheology.

The flexural rigidity of the lithosphere tends to increase with its thermal age (Fig. 3*a*), a result which is consistent with flexural results from both the oceans and continents^{1,12}. Fig. 3*a* shows

separate curves for 10^4 , 10^6 and 10^8 yr after loading. The kink in the curves at 100 Myr results from the dual quartz-olivine rheology of the continental lithosphere. The contributions of the quartz and olivine rheologies are illustrated in Fig. 3*b*, where flexural rigidity is plotted against the thermal age of the lithosphere at the time of loading for models which consist of composite quartz-olivine (crust-mantle) and all olivine compositions. For thermally younger, hotter lithosphere, the flexural rigidity is controlled by the crustal quartz rheology while for older, cooler lithosphere (>200 Myr), the flexural rigidity is controlled by the olivine rheology. Flexural rigidity increases rapidly in the region of 100 Myr thermal age as the quartz rheological control gives way to that of olivine. As quartz has such an important role in lithospheric flexure^{12,28}, so must, therefore, the crustal thickness. Figure 3*b* shows the effect of changing crustal thickness ($T=0, 20, 35$ and 60 km) and, not surprisingly, increasing the crustal thickness tends to decrease the flexural rigidity of the continental lithosphere until control is again passed back to the mantle olivine component for large thermal ages. In Fig. 3*b*, the predictions of the rheological model are also compared with those of a simple thermo-elastic flexure model¹³ in which the effective elastic thickness is controlled by a critical isotherm defining the elastic-plastic transition. For thermally younger lithosphere, when quartz rheology controls lithospheric strength, the 350 °C isotherm is the critical isotherm while for thermally older lithosphere, when olivine rheology is more important, it is the 550 °C isotherm.

Many intracratonic basins of continental interiors are characterized by finite stretching of the lithosphere²⁹⁻³⁶ and, as such, will modify the temperature and hence mechanical structure of the lithosphere. Stretching in our context increases the surface heat flow by a factor β during the rifting process²⁹. In fig. 3*c*, the pre-rift lithosphere has a continental average heat flow²² of 60 mW m^{-2} . The resulting thermal perturbation is important in

defining the transient temperature structure of the continents. The variable spatial and temporal distribution of intra-continental rifting may, however, result in a complex temperature structure²², but with each rifting event, the thermal perturbation will decay by conductive cooling of the continental lithosphere regardless of previous history or spatial complexity. Figure 3c shows the relationship between the stretching factor responsible for resetting the continental lithospheric thermal structure and the corresponding (post-stretching/rifting) temporal variation in flexural rigidity for values appropriate to basin formation ($2 < \beta < \infty$). The effect of increasing β is to reduce the flexural rigidity early in the post-stretch period, the effect rapidly diminishing with time.

The temperature structure of the lithosphere is strongly dependent on its assumed thickness and radioactive distribution. To contrast the 225-km lithospheric thickness model (with the radioactive distribution of Nicolayson *et al.*²⁴—representing an upper bound) so far used, a 125-km lithospheric thickness model (with the radioactive distribution of Sclater *et al.*²³) has also been considered (Fig. 3c). The 125-km plate model predicts significantly lower flexural rigidities relative to the 225-km plate model for thermal ages $> 10^8$ yr.

The temporal variation in flexural rigidity of the continental lithosphere is strongly modified by crustal thickness (quartzic component), lithospheric thickness (olivine component and thermal time constant) and the interaction of these factors during basin formation (lithospheric stretching and transient temperature structure). Observations of continental flexural rigidity (for which both the age of the load and thermal age of the basement are known; Table 1), when plotted against the thermal age of their respective basements, are not compatible with any one thermal/lithospheric model (Fig. 3d–f). Realistic variations in crustal thickness and lithospheric stretching lead to modelled rigidities which at least help us to understand the scatter within the observations.

The loading of thermally old lithosphere ($> 10^8$ yr) is associated with essentially a steady-state lithospheric temperature structure. However, loading of thermally young lithosphere (the lithospheric temperature structure, therefore, being transient) results in considerable scatter in the observed rigidities which, in part, is related to either crustal thickness or lithospheric stretching variations (Fig. 3d, e). The remaining scatter is almost certainly a result of the inability to assess accurately the past or present thermal age of the continental lithosphere, either because of the failure to reset radiometric ages within the upper crust (or that the reset region has yet to be exposed by erosion) or possibly because radiometric age resetting lags significantly behind load reactivation (that is rigidity resetting) due to the thermal diffusivity of the lithosphere. For example, even though the Molasse Basin developed on Hercynian crust, as evidenced by recovered basement in Austrian and Swiss exploration wells, the apparently anomalous flexural rigidity for the basin (see Fig. 3a, Table 1) may reflect a bias introduced by thermal activity associated with either the formation of the Rhine Graben and/or major Tertiary–Quaternary volcanic activity within Europe (for example, Chaine des Puys, Kaiserstuhl, Vogelsberg and northern Bohemia).

If the temperature structure of the continental lithosphere is governed by a cooling plate model, a unique steady-state temperature structure for old lithosphere, and thus a unique asymptotic flexural rigidity, is a reasonable expectation. While variations in crustal radioactive heat production may produce significant heat flow anomalies, they have a negligible effect on sub-crustal lithospheric temperature and hence flexural rigidity. The grouping of reliable flexural rigidities for thermally old continental lithosphere is consistent with a plate model for the thermal evolution of the lithosphere and further, suggests a steady-state lithospheric thickness of 175–225 km.

Although our discussion began with flexural rigidity, it concludes with a statement on lithospheric temperature structure. Flexural data, therefore, through thermo-mechanical modelling of lithospheric deformation, provides a powerful constraint on

both the transient and steady-state temperature structure of the continental lithosphere. The thermo-elastic model^{1,2,12} satisfies the general thermal age dependency as indicated by flexural observations, but the detailed time evolution of flexural rigidity after loading, which controls the details of sedimentary basin geometry and stratigraphy, can only be addressed by a thermo-mechanical flexural model which integrates laboratory-determined rock deformation data and transient lithospheric temperature structures associated with either intracratonic sedimentary basin formation or continental collisions, such as presented here.

Fossilized polyps in 430-Myr-old *Favosites* corals

Paul Copper

Department of Geology, Laurentian University, Sudbury, Ontario, Canada P3E 2C6

Tabulate corals are among the more characteristic fossils of the Silurian period, but because only their skeletons have been preserved, their taxonomic position and mode of life have been uncertain. Although they are generally placed¹ in the phylum Coelenterata (Cnidaria), the recent discovery of living sclerospores that share architectural affinity with some tabulates, has renewed debate about the evolutionary relationships of the latter. In particular, the tabulates have been assigned^{2,3} to the sponges (phylum Porifera). I report here the discovery of fossilized polyps in a *Favosites* from the Silurian of Quebec. This incontrovertibly demonstrates that the tabulates belong to the phylum Cnidaria, and details of the soft-part morphology suggest that the Tabulata form a group distinct from other corals.

Fig. 1 Calcified polyp structures preserved in the calices of a *Favosites* corallum from the Jupiter Formation (Silurian, Llandoveryan) of Anticosti Island, eastern Canada (specimen GS79441, Geological Survey of Canada, Ottawa). *a*, Overview of the hemispherical colony showing 109 corallites, most with centred polyps ($\times 3.75$); *b*, *c*, detailed view showing varied stages of polyp degradation ($\times 12.75$); *d*, inwardly retracted tentacles and gut cavity and concentrically layered, radially striated view of the lower polyp stalk ($\times 33.75$).

Favosites, like most of the tabulate corals, secreted a skeleton of calcite, unlike the modern scleractinians which favour aragonite. Some modern anthozoans, such as sea anemones, produce sizable, 60-mm diameter, trochoid chitinous shells resembling gastropod conchs⁴. However, there seems to be no record of calcified, silicified or phosphatized polyps. Polyp tissues are soft and contain no apparent mechanism for *in situ* precipitation of calcium carbonate. This is produced only by the basal disk tissues that secreted the calicular wall, septa and tabulae. The discovery of unmistakable calcified polyps, therefore, is both surprising and exciting.

Six well-preserved coralla of previously undescribed species of *Favosites* were collected from the basal 50 m of the Jupiter Formation (early Silurian, Llandoveryan, C¹-C²) of Anticosti Island, Quebec, Canada. Materials came from two different localities: A55, NTS 12° E/11° W 74800:89170 and A98, 12° E/12° E 53760-820:34770-880 in the central and southern parts of Anticosti. The specimen illustrated in Fig. 1 comes from the second locality (A98), in the basal 10 m of the Jupiter, a coastal bluff section of richly fossiliferous calcareous shales with interbedded, thinly bedded, micritic limestones. The fauna includes the brachiopods *Eocoelia hemisphaerica sefinensis*, *Atrypa* (*Gotatrypa*), *Triplesia anticostiensis*, *Pentamerus oblongus*, *Leptaena*, and small matchstick bryozoans along with small, hemispherical *Favosites*. No other corals, stromatoporoids or calcareous algae were found. The fauna is consistent with a late Llandovery (C¹-C²) age. The graptolite *Monograptus sedgwicki*

has been found some 40 m higher in the section. The type locality for the boundary between the Jupiter Formation and the underlying Gun River Formation is adjacent to the discovery site.

The corallum showing the best polyp preservation is hemispherical and 6 cm in diameter. Corallite diameters vary from 1.5 to 2.5 mm, with mural pores in the centre of the walls, variably developed short septa and very thin corallite walls (as verified in thin sections). The calices were freed from enveloping sediment by immersing the corallum in Quaternary O for 1 h and cleaning in an ultrasonic bath for 80 min.

More than 200 of the corallites on the surface of the specimen in Fig. 1 showed the attachment of polyp structures preserved as calcite. Polyps were seen in a 'retracted' position, that is with the tentacular ring inwardly bent and tentacles inwardly directed. Tentacles tapered and were blunt-ended. Of more than 300 corallites measured in one corallum, ~70% had polyps preserved in varied stages of degradation from only the remnants of a basal disk, to those with shrunken tentacles, to fully displayed structures (Fig. 1). The fossilized polyps occupy about two-thirds of the calice: this is not significant because the fully extended polyps of living corals can be inflated to several times the corallite diameter. The concentric wrinkles at the base of the polyp stalk and fine radial elements similar to those seen in modern corals⁵ were also preserved (Fig. 1d).

The average number of individual tentacles measured for well-preserved polyps was 12; a few had 11 or 13 tentacles. No particular enlargement, division or symmetry of tentacles was

observed, suggesting that the tentacles were uniformly sized in *Favosites*, that is no 'sweeper' tentacles were indicated. The number of septal spines in the thin sections of *Favosites* examined was difficult to study as septal insertion was uneven or arrhythmic, and the septal spines were upwardly directed. However, *Astrocerium*, a close Silurian relative of *Favosites*, is characterized by 12 regular rows of septa. The Silurian heliolitid tabulates are also typified by 12 septa. The significance of the relationship between the discovery of 12-fold tentacles and the occurrence of 12 septa in several groups of tabulates is unclear. There may be no direct relationship.

The discovery of tentacular polyps in *Favosites* discards the possibility that the Favositidae, and probably other tabulates, are aberrant members of the Phylum Porifera, as has been suggested recently. Their taxonomic affinities seem to lie clearly with the Cnidaria.

The development of a common scheme of 12 tentacles for each polyp suggests the possibility of dodecal symmetry in the Favositidae. This, along with the known presence of 12 septa in other tabulates, seems to set the Tabulata away from the tetracorals (*Rugosa*), hexacorals (*Scleractinia*) and octocorals (*Octocorallia*).

The method of polyp calcification is as yet undetermined. In the absence of unusual environmental conditions on the stable marine carbonate platform of Anticost Island during the Silurian, it is tempting to suggest that algal symbionts were present in the tabulates and that these may have initiated precipitation of calcite nuclei or spicules inside the polyp. There is no evidence for this at present, as it is not clear whether calcification occurred while the polyp was alive or immediately after death. If algal symbionts were pervasive in the tabulates it is difficult to understand why polyp preservation is so rare.

Paternal cyclophosphamide treatment of rats causes fetal loss and malformations without affecting male fertility

Jacquetta M. Trasler, Barbara F. Hales & Bernard Robaire

Centre for the Study of Reproduction, Departments of Pharmacology and Therapeutics and of Obstetrics and Gynecology, McGill University and the Royal Victoria Hospital, 3655 Drummond Street, Montreal, Quebec, Canada H3G 1Y6

The use of cytotoxic, mutagenic and carcinogenic agents as treatment for various types of cancer may be particularly hazardous in men of reproductive age as there exists the possibility that this may lead to congenital malformations in the progeny. Such agents can affect fertility and other aspects of male reproductive function, for example, treatment with anti-cancer drugs such as cyclophosphamide has been associated with oligozoospermia, azoospermia and increased levels of serum follicle-stimulating hormone (FSH)^{1,2}. Depending on the cumulative dose and the duration of treatment, spermatogenesis often returns but this may take years^{3,4}. The relevance of the effects of such chemicals on the male reproductive system to the offspring is poorly understood. We have set out to determine whether present tests of male reproductive function (that is, endocrine status, numbers of spermatozoa, fertility) can predict deleterious effects of a paternally administered agent on the offspring. Here, we report that chronic administration in rats

Fig. 1 Effects on the progeny from matings at specified times after initiation of paternal treatment with saline (□) or 5.1 mg per kg per day of cyclophosphamide (▨) by gavage. The mating schedule used allows an assessment of the stage of spermatogenesis affected by cyclophosphamide. Effects on the progeny after 1-2 weeks of treatment of the male indicate that epididymal spermatozoa were affected; similarly, after 3-4 weeks the germ cells affected were spermatids; after 5-6 weeks spermatocytes; and after 7-9 weeks spermatogonia⁷. Pre-implantation loss (a) is defined as the number of corpora lutea minus the number of implantations divided by the number of implantations. Post-implantation loss (b) is defined as the number of implantations minus the number of resorptions divided by the number of implantations. Both these values are expressed as per cent mean per litter. Fetuses were examined for gross malformations. External malformations (c) are expressed as the per cent of malformed fetuses divided by the total number of live fetuses for a given time period. Control and treatment groups were compared using a Fisher exact test¹⁰. The level of significance is taken as $P \leq 0.05$ throughout.

of low doses of the widely used drug cyclophosphamide had minimal effects on the male reproductive system and fertility, but resulted in malformations and retardation of growth in the surviving fetuses and a high frequency of fetal death. Thus, adverse effects on the fetus cannot be predicted from the effects of a drug on the male reproductive system.

Cyclophosphamide (CP) was chosen for this study as it is widely used clinically as an anti-cancer agent and has also been associated with variable periods of infertility in humans³. Adult male Sprague-Dawley rats were treated daily six times a week for 11 weeks by gavage with either saline solution (control) or one of three doses of CP (1.4, 3.4 and 5.1 mg per kg per day). These daily low-dose regimens simulated maintenance regimens used clinically for cancer treatment⁵. The 77-day treatment period covers one full cycle of the seminiferous epithelium (51.6 days) as well as the time needed for epididymal transit of the sperm (~10 days)^{6,7}. Thus, effects that are seen after the first 1-2 weeks of treatment reflect an action of the drug on spermatozoa undergoing maturation in the epididymis. Effects first seen 3-4 weeks after the initiation of treatment reflect action of the drug on spermiogenesis (spermatid development) or post-spermiogenesis changes, while effects first seen after 5-6 weeks of treatment indicate an effect on spermatogenesis or subsequent stages. An effect that selectively occurs 7-9 weeks after initiation of treatment would suggest strongly an effect on the proliferative spermatogonial phase of spermatogenesis.

The male rats were killed after 11 weeks and the effects of

Table 1 Effects of chronic treatment with cyclophosphamide for 11 weeks on the reproductive system of male rats

Treatment group	Body weight (g)		Tissue weight (g)		Sperm reserves ($\times 10^6$)*	Serum hormones (ng ml ⁻¹)		
	Initial	Final	Ventral prostate	Cauda epididymis		LH	FSH	Testosterone
Saline	317 $\pm$ 4	500 $\pm$ 14	0.57 $\pm$ 0.08	0.57 $\pm$ 0.02	152 $\pm$ 15	0.52 $\pm$ 0.06	193 $\pm$ 28	2.6 $\pm$ 0.6
Cyclophosphamide								
1.4 mg per kg per day	319 $\pm$ 5	534 $\pm$ 11	0.61 $\pm$ 0.06	0.52 $\pm$ 0.03	188 $\pm$ 17	0.43 $\pm$ 0.09	186 $\pm$ 28	2.2 $\pm$ 1.0
3.4 mg per kg per day	317 $\pm$ 3	481 $\pm$ 24	0.59 $\pm$ 0.05	0.59 $\pm$ 0.02	166 $\pm$ 15	0.36 $\pm$ 0.06	174 $\pm$ 21	1.8 $\pm$ 0.3
5.1 mg per kg per day	325 $\pm$ 4	484 $\pm$ 16	0.48 $\pm$ 0.04	0.59 $\pm$ 0.03	177 $\pm$ 17	0.38 $\pm$ 0.07	198 $\pm$ 13	2.4 $\pm$ 0.8

The serum concentrations of luteinizing hormone (LH), FSH¹⁸ and testosterone¹⁹ were measured by radioimmunoassay. For LH, NIH RP-2 preparations were used as standards. Numbers of spermatozoa in the cauda of the epididymis were determined by the method of Robb *et al.*²⁰ as modified by Scheer and Robaire¹⁹. Data were analysed by one-way analysis of variance with the new Duncan's multiple-range test²¹. Values are the mean $\pm$ s.e.m. The level of significance is taken as $P \leq 0.05$ throughout.

* Sperm reserves represent spermatozoal numbers in the cauda of the epididymis.

the drug treatment were assessed on the basis of body and reproductive organ weights, serum hormone levels and epididymal spermatozoal numbers. To assess the effects of the treatment on the progeny, each male ($n = 6$ per group) was mated overnight with two pro-oestrous females on day 7 of weeks 1 to 7 and 9 of treatment. Males were not treated with CP on the day of mating in order to preclude a direct effect of the drug on fertilization and post-fertilization events by transfer via the seminal fluid⁸. Females ($n = 384$) were killed 20 days after mating and caesarian sections were performed. The rate of embryo or fetal loss was determined by counting numbers of corpora lutea, implantations and resorptions, and the live fetuses were examined for external malformations.

The effects of the drug treatment on the male reproductive system of the rat are shown in Table 1. The similarities of initial and final body weights between the control and treated groups show that the treatment did not apparently affect the general health of the animals. There was no significant change in the weights of the male reproductive organs, in reserves of spermatozoa or in serum hormones reflecting male endocrine status in any of the CP-treated animals (Table 1). Ventral prostate and caudal epididymal weights were unchanged; testis, seminal vesicle and pituitary weights were also similar in the different groups (data not shown). As CP is an alkylating agent that causes most damage to rapidly dividing cells, the drug was expected to affect the seminiferous epithelium and reduce the number of spermatozoa produced. The number of spermatozoa in the cauda of the epididymis provides a good estimate of spermatozoal reserves⁹; clearly these reserves were not affected by the treatment regimen. These results suggest that the proliferative phase of spermatogenesis is unaffected by the cytotoxic effects of CP.

The mating ability and fertility of the males was similar in all groups, as assessed by counting seminal plugs on the morning after mating and the number of pregnant females per group. The number of plugs was similar for all treatment groups (in the range 3.6 ± 0.2 to 4.0 ± 0.2 ; mean $\pm$ s.e.m.). The number of pregnant females per sperm-positive females also did not differ between groups (91–97%). Clearly, the daily doses of CP used in these experiments did not affect the weight gain, endocrine status, spermatozoal reserves or the fertility of the treated males.

In view of the minimal effects of the CP treatment on the male reproductive system, the varied and complex effects on the progeny were quite unexpected. For clarity, only the results for the control and the group treated with 5.1 mg per kg CP are illustrated (Fig. 1). Results for the groups treated with 1.4 and 3.4 mg CP per kg fell between those for the control group and the groups treated with 5.1 mg CP per kg, in a dose-dependent fashion for all parameters. The control level of pre-implantation loss was relatively constant over the 9 weeks of mating (mean 7%, range 3–11%). Pre-implantation loss was low during the first 2 weeks of CP treatment, gradually increased between weeks 3 and 6, and was significantly ($P \leq 0.01$) greater than the control by weeks 5–6. However, this increase disappeared by weeks 7–9.

Thus pre-implantation loss occurred when germ cells were first exposed as spermatocytes or late spermatids.

There was a dramatic dose-dependent increase in post-implantation loss after week 2 ($P \leq 0.001$) for all animals receiving CP (Fig. 1); after week 4 a plateau of 80% loss was reached and maintained until weeks 7–9 ($P \leq 0.001$). The most striking increase in post-implantation loss occurred between weeks 2 and 4 when germ cells were first exposed as spermatids. To determine the timing of post-implantation loss, resorptions were weighed and defined as early (<100 mg) or late (>100 mg). Analysis of the weights of the resorptions revealed that this increase in post-implantation loss was due mainly to an increase in early resorptions; 87% of resorptions occurred early in gestation in the control group whereas 98% occurred early in the CP-treated group. Thus paternal treatment with CP resulted in germ-cell damage that was incompatible with development beyond organogenesis in a high percentage of embryos.

The CP-induced pre- and post-implantation losses resulted in a dose- and time-dependent decrease in the number of live fetuses per litter. While no increase of abnormalities was apparent in live offspring from matings at 1–2 weeks (control = 0/196, CP-treated = 0/184) and 5–6 weeks (control = 1/151, CP-treated = 0/55), the frequency of abnormalities was increased in offspring from matings at 3–4 weeks (control = 0/231, CP-treated = 3/93; $P < 0.02$) and at 7–9 weeks (control = 1/254, CP-treated = 4/57; $P \leq 0.005$). The most common abnormalities seen were hydrocephalus, micrognathia and oedema. There was also an increase in the percentage of growth-retarded or low-weight fetuses (fetuses weighing $<75\%$ of the mean weight for their group) in the offspring from matings at 3–4 weeks (control = 1.3%, CP-treated = 4.3%, $P \leq 0.10$) and at 7–9 weeks (control = 1.2%, CP-treated = 7.0%; $P \leq 0.02$, Fisher exact test¹⁰). (The dose of CP in all the above treatments was 5.1 mg per kg.)

Thus, paternal treatment with CP causes pre-implantation loss when germ cells were first exposed as spermatocytes or late spermatids. Post-implantation loss increased at the greatest rate when germ cells were first exposed as spermatids. There was a significant increase in external malformations and growth-retarded fetuses among the offspring when germ cells were first exposed as either spermatids or spermatogonia. Clearly, the low numbers of malformed fetuses involved make it difficult to elucidate the stage(s) of spermatogenesis affected. Different underlying mechanisms, both genetic and non-genetic, could be postulated to explain the effects, based on the fact that germ cells are first exposed to CP when they are undergoing different processes: spermatozoal maturation (1–2 weeks), cytoplasmic reorganization and chromatin condensation of spermiogenesis (3–4 weeks), meiosis during spermatocytogenesis (5–6 weeks) and active mitotic division (7–9 weeks).

Obviously, there are some severe qualitative changes in the spermatozoa of the treated males that are not manifested by concomitant quantitative changes. The effects seen are probably not due to a cumulative effect of CP in seminal fluid as: (1) the

drug has a short half-life in rodents and man and is eliminated within hours of ending chronic treatment^{11,12} (our protocol allowed 36 h between drug administration and mating); and (2) in the present study, there was no cumulative increase in pre-implantation loss and external malformations with increasing time of paternal drug exposure.

Previous studies in rats indicate that, after paternal treatment, CP can cause a decrease in litter size^{13,14} and lead to dominant lethal mutations¹⁵ as well as behavioural abnormalities in the surviving offspring¹⁴. Although the mechanism(s) underlying paternally mediated effects of CP on the outcome of pregnancy remains unresolved, one possibility is that this drug affects the genetic composition of the spermatozoa—CP has been shown to induce sister chromatid exchange and chromosomal aberrations in male germ cells^{16,17}. In addition, clinical studies have indicated that CP can affect the human male reproductive system¹. As far as we are aware, no study to date has attempted to relate effects on the male reproductive system to the outcome in the progeny. Thus, we have demonstrated, for the first time, that paternal treatment of rats with a commonly used antitumour drug can cause malformations and growth retardation of the surviving offspring and lead to dramatic embryo loss, while at the same time having minimal effects on the male's endocrine status or spermatozoal reserves.

The J1 glycoprotein—a novel nervous system cell adhesion molecule of the L2/HNK-1 family

Jan Kruse, Gerhard Keilhauer, Andreas Faissner, Rupert Timpl* & Melitta Schachner†

Department of Neurobiology, University of Heidelberg, Im Neuenheimer Feld 504, D-6900 Heidelberg, FRG

* Max-Planck-Institut für Biochemie, 8033 Martinsried, FRG

The neural cell adhesion molecules L1 (refs 1, 2) and N-CAM (refs 3-5) share a common carbohydrate epitope that is recognized by the monoclonal antibodies L2 and HNK-1 (ref. 6). The L2/HNK-1 epitope is also present on the myelin-associated glycoprotein (MAG) which is thought to mediate surface interactions between the axon and myelinating cell⁷. Other, as yet unidentified,

cell-surface glycoproteins are recognized by the two antibodies and are believed to belong to a family of neural cell adhesion molecules^{1,2,6}. To test this hypothesis, we have prepared polyclonal antibodies to a prominent member of the L2/HNK-1 family, the 160K (relative molecular mass (M_r) 160,000) glycoprotein. Here we report that these antibodies, designated J1 antibodies, react with astrocytes and oligodendrocytes and interfere with neurone-astrocyte adhesion, but not with neurone-neurone or astrocyte-astrocyte adhesion. This result suggests the involvement of the J1 antigen in cell-cell interactions.

J1 antibodies do not react with L1, N-CAM or MAG (Fig. 1a-c), but react specifically with the 160K component of 'rest L2' (ref. 6; see Fig. 1 legend) from adult mouse brain (Fig. 1c). During cerebellar development the antigen is faintly detectable in Western blots of a crude membrane fraction at embryonic day 15, in the form of two faint bands with apparent M_r s of 220K and 200K (Fig. 1g). With increasing age, immunoreactivity shifts from the 220K and 200K bands towards the 160K band (Fig. 1h-k). In the adult form the 220K component is no longer present (Fig. 1c, l). When J1 antigen is isolated preparatively from 'rest L2' of adult brain, the 200K component is not detectable, possibly because of degradation during purification procedures. The J1 antigen is a glycoprotein, as it can be biosynthetically labelled with fucose (Fig. 1m) and is recognized by monoclonal antibody L2 (result not shown). Cultured astrocytes (Fig. 1n), but not neurones (Fig. 1o) purified from early postnatal cerebellum, synthesize the 220K form; this component is also secreted into the culture supernatant. In mixed cerebellar cultures the antibody reacts strongly on immunofluorescence with glial fibrillary acidic protein (GFAP)-positive astrocytes, with O4 and O1 antigen-positive oligodendrocytes (Fig. 2) and with some fibronectin-positive fibroblast-like cells (not shown). Neurones acquire faint immunoreactivity with time in culture, possibly resulting from adsorption of the secreted 220K form of the antigen. As the J1 antigen is secreted into the culture medium, we examined its possible relationship to characterized extracellular matrix proteins. Radioimmunoassays, however, fail to detect any significant reaction of J1 antibody with laminin⁸, collagen IV⁹, fibronectin, nidogen¹⁰ or heparan sulphate proteoglycan¹¹ (results not shown).

When adhesion of single-cell suspensions to monolayer cells is measured in the presence of Fab fragments of J1 antibody, neurone-astrocyte adhesion is inhibited, but not astrocyte-astrocyte or neurone-neurone adhesion (Table 1). The low level of adhesion between neurones and skin fibroblasts is also not disturbed to any measurable degree by J1 antibodies (not shown). That J1 antibodies do not interfere with adhesion of neurones to J1 antigen-positive skin fibroblasts could be the result of a molecular difference or a difference in cell-surface density of the J1 antigen between astrocytes and fibroblasts. Fab fragments of polyclonal antibodies to mouse liver membranes do not interfere with adhesion (Table 1), whereas polyclonal L1 antibodies prevent neurone-neurone adhesion, and polyclonal N-CAM antibodies prevent neurone-neurone, neurone-astrocyte and astrocyte-astrocyte adhesion (results not shown; see ref. 12).

The present experiments have revealed a novel neural cell adhesion molecule, the J1 antigen, which mediates neurone-astrocyte adhesion and may provide the molecular basis for the repeatedly observed preferential attachment of neuronal cell bodies to astrocytes, and the accelerated neurite extension on astrocyte membranes. As a secreted glycoprotein, J1 antigen may represent part of the extracellular matrix in the nervous system. As J1 antigen is synthesized by astrocytes and not by neurones, an adhesion mechanism between J1 glycoprotein(s) and a different receptor molecule(s) on neurones must be postulated. Whether L1 or N-CAM is involved in such ligand-receptor relationships, and whether J1 antigen contributes to the migration of granule cell neurones along the surface of Bergmann glial processes, remains to be seen.

J1 antigen is the third member of the L2/HNK-1 family of cell-surface glycoproteins to be examined for its involvement in

† To whom correspondence should be addressed.

Fig. 1 Immunochemical characterization of the J1 antigen. In Western blots, the J1 antibody did not react with immunopurified L1 (a) or N-CAM (b), and recognized the 160K component, but not the myelin-associated glycoprotein (MAG), the 100K component of 'rest L2' (c). Compare the Western blots (a-c) with the immunopurified L1 (d), N-CAM (e) and 'rest L2' (f) from adult mouse brain in reduced silver gels according to Merrill¹⁹. During cerebellar development, J1-immunoreactive material was examined by Western blot analysis of crude membrane fractions¹⁵ of C57BL/6J mice, after SDS-polyacrylamide gel electrophoretic separation on 6-12% gels with 200 µg protein per well, at embryonic day 15 (g), at postnatal days 0-2 (h), 4-6 (i), 8-12 (j) and 20-25 (k) and in the adult (>2 months old; l). m, J1 antigen is a glycoprotein, as it incorporates ³H-fucose into the 220K band; the lane shows an autoradiograph of an immunoprecipitate with J1 antibody. J1 antigen can be immunoprecipitated from cultures of pure astrocytes (>97% are positive for the astrocyte marker GFAP) as

as a strong 220K band (n) and as a very faint band from pure neurones (o) (>99% are positive for the neurone markers L1 antigen and tetanus toxin receptor) isolated from early postnatal mouse cerebellum as described elsewhere¹². The weak reactivity of the neuronal cultures is presumably caused by low contaminating levels of astrocytes and fibroblast-like cells. p, Autoradiograph of an immunoprecipitate from astrocytes reacted with preimmune rabbit antibodies. Arrows indicate the 160K, 200K and 220K components of J1 antigen.

Methods. Polyclonal antibodies were prepared in rabbits by injecting them with 160K glycoprotein isolated from adult mouse brain. The 160K band was purified from 'rest L2' (consisting of the L2 epitope-carrying molecules after removal of L1 antigen and N-CAM by immunoaffinity chromatography on monoclonal L1 and H28.123 (mouse N-CAM/BSP-2) columns⁶). 'Rest L2' was separated by chromatography on a Sephacryl S-300 column in Tris-buffered saline pH 8.2, containing 0.1% deoxycholate. The fractions containing the 160K glycoprotein were used for immunization. The pooled fractions were checked for purity in Western blots, which showed no reaction with polyclonal L1, N-CAM and MAG antibodies. On incubation with monoclonal L2 antibodies, the fractions showed mainly one broad band at 160K. This band was also the predominant one in SDS silver gels. Outbred rabbits were injected subcutaneously with 10 µg of purified 160K component in Tris-buffered saline, first in complete Freund's adjuvant and 2-3 weeks later in incomplete Freund's adjuvant. Seven days after the third intraperitoneal injection of 10 µg J1 antigen in Tris-buffered saline, rabbits were bled for serum. The purified IgG fraction of J1 antibodies was used in all experiments. ³H-fucose labelling was carried out in mixed cerebellar cultures¹⁶ from 6-day-old C57BL/6J mice (1×10^7 cells in a Petri dish of 6 cm diameter). After 3 days *in vitro*, cells were treated with ³H-fucose ($80 \mu\text{Ci ml}^{-1}$) in 1 ml of basal Eagle's medium containing 10% horse serum¹⁶ for 4 h in a CO₂ incubator, subsequently solubilized and used for immunoprecipitation as described previously¹². Immunoprecipitations of ³⁵S-methionine-labelled cells were carried out as described in detail elsewhere¹².

Fig. 2 Double immunofluorescence for J1 antigen (c, f) in monolayer cultures of 7-day-old C57BL/6J mouse cerebellum after 2 days *in vitro*; and for glial fibrillary acidic protein (b) and the oligodendrocyte marker O4 (e). a, d, Corresponding phase-contrast micrographs of the fluorescence images b, c and e, f, respectively. The procedures for cell culture and double immunofluorescence have been described elsewhere¹⁴⁻¹⁶. $\times 320$.

Table 1 Inhibition of adhesion between neurones and astrocytes from early postnatal mouse cerebellum in the presence of Fab fragments from J1 antibody

Antibody	Fab concentration (mg ml ⁻¹)	Neurone-neurone	Neurone-astrocyte	Astrocyte-neurone	Astrocyte-astrocyte
None	0	0 ± 3	0 ± 2	0 ± 4	0 ± 2
Polyclonal antibody to mouse liver	1	2 ± 4	-3 ± 2	-2 ± 3	1 ± 1
J1	1	-3 ± 8	47 ± 7	38 ± 15	-7 ± 12

The adhesion test was carried out as described elsewhere¹² using monolayer cultures as target cells and fluorescein diacetate-labelled single-cell suspensions as probe cells. Pure populations of astrocytes and neurones were obtained by buoyant density centrifugation of single-cell suspensions through Percoll, combined with immunocytolysis¹². Small cerebellar neurones were obtained from 6–8-day-old C57BL/6J mice and used as target cells after 3 days in culture, with over 99% of all cells expressing L1 antigen¹⁵ or tetanus toxin receptors¹⁶ and less than 1% expressing J1 antigen. Cerebellar astrocytes were obtained as described elsewhere¹² from 3–5-day-old mice by immunocytolysis with O4, MESA-1 and M5 antibodies in the presence of guinea pig complement, after 3 days of *in vitro* culture and subsequent subculture for 1 day; over 97% of all the cells expressed GFAP and more than 95% expressed J1 antigen. Fibroblasts were obtained from the skin of 1-day-old C57BL/6J mice by treatment with collagenase IV and trypsin¹⁷ and used as target cells after 3 days of *in vitro* culture. Over 90% of these cells expressed the J1 antigen. Probe cells were obtained from monolayer cultures of enriched neurones (after 1 day in primary culture), astrocytes (1 day after immunocytolysis and subsequent subculture) and fibroblasts (after 3 days in primary culture) by treatment with 20 µg ml⁻¹ trypsin, 1 mM EDTA in Ca²⁺, Mg²⁺-free Hank's balanced salt solution for 15 min at room temperature¹². Probe cells were labelled with fluorescein diacetate (10⁻⁶ M) during the trypsinization step. The mild trypsin treatment did not reduce the immunofluorescence staining intensities for either the J1 antibody or the antibody to mouse liver membrane¹⁸, as judged by comparison with non-trypsinized cells. Probe and target cells were treated with Fab fragments of J1 antibody for 20 min on ice before the adhesion test. Probe and target cells were then incubated for 30 min at room temperature in a reciprocal shaker at 40 cycles per min. Aggregation among probe cells was negligible in the presence or absence of Fab fragments. In the absence of Fab fragments the percentage of binding of total input cells was ~80% for neurone-neurone and neurone-astrocyte adhesion, 50% for astrocyte-astrocyte and astrocyte-neurone adhesion, and 10% for neurone-fibroblast adhesion (see ref. 12 for details). Per cent inhibition of adhesion in the presence of Fab fragments was calculated from:

$$\% \text{inhibition} = \left(\frac{\text{adhesion (control)} - \text{adhesion (+Fab)}}{\text{adhesion (control)}} \right) 100$$

Values are the mean of several experiments (±s.d.). Three experiments were performed for neurone-neurone adhesion, three for neurone-astrocyte adhesion, two for astrocyte-astrocyte, two for astrocyte-neurone and two for neurone-fibroblast adhesion. The difference in inhibition of adhesion due to liver membrane and J1 antibodies is significant for neurone-astrocyte and astrocyte-neurone adhesion ($P < 0.001$, Student's *t*-test).

cell-cell interactions, and indeed it has been shown to mediate adhesion. This result is in accord with our hypothesis that all L2/HNK-1-carrying molecules are functionally important in cell-surface interactions^{2,6}. The observation that further glycoproteins belong to the L2/HNK-1 family may now encourage and guide further search for new adhesion molecules displaying different sets of functional properties not only in the nervous system, but also in the immune system, where HNK-1 has been shown to react with a subclass of lymphocytes including natural killer cells¹³. The fact that all neural adhesion molecules identified so far share a carbohydrate moiety which is involved in adhesion¹², which appears to be developmentally regulated independently from the expression of the protein backbone of the adhesion molecule¹⁴, and which is differentially expressed on some, but not all N-CAM molecules⁶, indicates an important functional role¹² that is highly conserved among vertebrate species and which has yet to be elucidated in molecular terms.

We thank L. Eng and W. W. Franke for antibodies, B. Bizzini for tetanus toxin, Studienstiftung des Deutschen Volkes for a doctoral fellowship (to G. K.) and Deutsche Forschungsgemeinschaft for support.

Pertussis toxin reverses adenosine inhibition of neuronal glutamate release

A. C. Dolphin & S. A. Prestwich

Department of Pharmacology and Clinical Pharmacology, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE, UK

Adenosine and its analogues are potent inhibitors of synaptic activity in the central and peripheral nervous system^{1,2}. In the central nervous system (CNS), this appears to arise primarily by inhibition of presynaptic release of transmitters^{3,4}, including glutamate⁵, which is possibly the major excitatory transmitter in the brain. In addition, postsynaptic effects of adenosine have been reported which would also serve to reduce neurotransmission^{6,7}. The mechanism by which adenosine inhibits CNS neurotransmission is unknown, although it appears to exert its effect via an A₁ receptor^{2,8} which in some systems is negatively coupled to adenylate cyclase⁹. In an attempt to elucidate the mechanism of inhibition, we have examined the effect of pertussis toxin (PTX) on the ability of the stable adenosine analogue (–)-phenylisopropyladenosine (PIA) to inhibit glutamate release from cerebellar neurones maintained in primary culture. PTX, by ADP-ribosylating the nucleotide-binding protein N_i, prevents coupling of inhibitory receptors such as the A₁ receptor to adenylate cyclase¹⁰. As reported here, we found that PTX, as well as preventing inhibition of adenylate cyclase by PIA, also converts the PIA-induced inhibition of glutamate release to a stimulation. Our results suggest strongly that purinergic inhibitory modulation of transmitter release occurs by inhibition of adenylate cyclase.

Although previous experiments concerning the effects of adenosine on transmitter release from brain tissue have been performed on slices or synaptosomes, our preliminary results indicated that incubation of hippocampal slices (300 µm thick) for 1 h with PTX (0.1–1.0 µg ml⁻¹) had no effect on the ability of the adenosine analogue 2-chloroadenosine to inhibit trans-

Fig. 1 Effect of incubation of cultured cerebellar neurones with PTX on (-)PIA-induced inhibition of adenylyl cyclase in membranes prepared from the cells. We investigated the effect of (-)PIA on the stimulation of adenylyl cyclase by a submaximal concentration of forskolin (2 μM). The basal adenylyl cyclase activity was 8.3 ± 3.5 and 8.9 ± 2.7 pmol per min per mg protein and the forskolin-stimulated activity was 14.7 ± 2.4 and 33.3 ± 8.8 pmol per min per mg protein in control (●) and PTX-treated (○) cells respectively (mean $\pm$ s.e.m.). Numbers in parentheses indicate number of experiments.

Methods. Rat cerebellar neurones were grown on poly-L-lysine in 35-mm Petri dishes for 13–21 days, having been treated with fluorodeoxyuridine (80 μM) after 2 days *in vitro* to reduce non-neuronal cell proliferation. They were incubated for 14–16 h at 37 °C with either PTX (0.5–1.0 μg ml⁻¹) or its vehicle (1 M NaCl, 10 mM Tris-HCl pH 8, diluted 100-fold) in 0.5 ml of growth medium (minimal essential medium (MEM), 10% fetal calf serum, 25 mM KCl). The cells were rinsed with buffer and collected in 10 mM Tris-HCl, 2 mM EGTA pH 7.4. After homogenization, the membranes were washed twice and adenylyl cyclase activity was assayed as described in ref. 13, except that EGTA (0.5 mM) was present in the final incubation medium and incubation was continued for 20 min.

mitter release (A.C.D. and E. R. Archer, unpublished data). As incubation of slices for longer periods markedly decreased the ability of the slices to synthesize and release glutamate, the effect of incubation with PTX for longer time periods was not examined. Instead, we examined the effects of PTX in a cell culture system. Cerebellar cells cultured from 3–6-day-old rats consist mainly of granule cells and have previously been found to release glutamate on depolarization, in a Ca²⁺-dependent manner¹¹. The neurones were grown, as described previously^{11,12}, on coverslips for the transmitter release studies (for method see Fig. 2 legend). For each experiment, we determined the amount of newly synthesized ³H-glutamate released in two periods of depolarizing stimulation (S₁ and S₂; see Fig. 2 legend). The S₂/S₁ ratio was then compared between experiments.

In adult animals, A₁ adenosine receptors have been shown to be associated with cerebellar granule cells¹³; in agreement with this observation, in our initial studies we found that inhibition of ³H-glutamate release by (-)PIA, which is a relatively selective A₁ agonist, developed at the same time as stimulus-dependent transmitter release became maximal, between 7 and 12 days *in vitro*, depending on the batch of neurones. For example, between days 7 and 9 *in vitro*, stimulation with 50 μM veratridine caused release of $1,553 \pm 332$ d.p.m. ($n=6$) over basal levels of ³H-glutamate and (-)PIA (2 μM) inhibited release by $12.1 \pm 1.2\%$ ($n=3$), whereas between days 14 and 21 *in vitro*, the same stimulus resulted in release of $2,860 \pm 713$ d.p.m. ($n=8$) of ³H-glutamate and inhibition by (-)PIA was $57.0 \pm 13.1\%$ ($n=4$). In subsequent experiments, neurones were used between days 13 and 21 *in vitro*.

When cultured neurones were incubated with PTX for 14–16 h, the inhibition of adenylyl cyclase by (-)PIA seen in washed membranes prepared from a cell-free preparation of control cells (preincubated with vehicle) was converted to a marked stimulation (Fig. 1). This result not only indicates that in these cells PTX is effective in preventing negative coupling to adenylyl cyclase, in parallel with its effect in other sys-

Fig. 2 Effect of PTX on the inhibition by (-)PIA of ³H-glutamate release from cultured cerebellar neurones. The amount of ³H-glutamate released after stimulation was calculated by subtracting the averaged basal release, and the ratio S₂/S₁ was determined for each experiment. A pair of control (open columns) and (-)PIA (solid columns) experiments were performed on the same day on the same batch of neurones, and the significances of the differences between their S₂/S₁ ratios (given as mean $\pm$ s.e.m.) were determined by paired t-tests. * $P < 0.05$; † $P < 0.01$. The outflow of ³H-glutamate (in d.p.m.) during S₁ for control (a) and PTX-treated (b) neurones was, respectively, $4,899 \pm 1,452$ and $5,423 \pm 1,410$ for K⁺ stimulation, and $1,979 \pm 264$ and $2,868 \pm 509$ for veratridine stimulation. The increases due to PTX treatment did not reach statistical significance.

Methods. Neurones (13–21 days *in vitro*), grown on 1-cm² coverslips, were preincubated for 14–16 h at 37 °C with PTX (0.5–1.0 μg ml⁻¹) or its vehicle in 100 μl growth medium. They were then rinsed and incubated with ³H-glutamine (5 μCi in 100 μl of Krebs-Ringer buffer (KRB) pH 7.4; 320 mM) for 45 min. The coverslips were rinsed and transferred to a perfusion chamber¹² and perfused with KRB at 35 °C at a rate of 1 ml min⁻¹. Two periods of stimulation were applied 18 min (S₁) and 36 min (S₂) after the start of perfusion, with either 50 mM K⁺-KRB for 4 min or 50 μM veratridine-KRB for 3 min. To examine the effect of (-)PIA (2 μM), it was included in the KRB from 27 min after the start of perfusion. Fractions collected at 1-min intervals were placed in tubes containing 10 mM each of carrier glutamine, glutamate and γ-aminobutyric acid (GABA) and 1.5 nCi of ¹⁴C-glutamate to correct for recovery. The ³H-glutamate in the fractions was separated from labelled glutamine and GABA by column chromatography as described previously⁵.

tems^{14,15}, but also that PTX treatment allows the expression of an underlying stimulation of adenylyl cyclase, possibly via A₂ receptor activation.

We then examined the effect of PTX on the ability of (-)PIA to inhibit depolarization-induced release of newly synthesized glutamate. In control experiments in the absence of (-)PIA, PTX altered the pattern of release of ³H-glutamate, in that the S₂/S₁ ratio was reduced in PTX-treated compared with control cells (Fig. 2). It is possible that the enhanced release of ³H-glutamate in S₁ relative to S₂ in PTX-treated cells results from either an increased concentration of endogenous cyclic AMP or the inability of endogenously released adenosine to inhibit glutamate release in PTX-treated cells. Because of the finite amount of ³H-glutamate available for release, there would be a corresponding reduction in S₂ and thus a reduction in the S₂/S₁ ratio.

We observed a more marked effect of PTX treatment on the response to PIA. Whereas in control cells (-)PIA (2 μM) inhibited both veratridine- and K⁺-stimulated release of ³H-glutamate by 55 and 28%, respectively (Fig. 2a), in PTX-treated cells there was a marked enhancement of ³H-glutamate release in the presence of (-)PIA (Fig. 2b), by 87 and 117% for veratridine and K⁺ stimulation, respectively.

The conversion of (-)PIA-induced inhibition of ³H-glutamate release to a stimulation by pretreatment with PTX mirrors the effect of PTX on adenylyl cyclase in these cells. In addition, in control intact cerebellar neurones, synthesis of cyclic AMP is enhanced by the depolarizing stimuli used, and PIA inhibits both control and K⁺-stimulated cyclic AMP production (A.C.D. and S.A.P., preliminary results). We suggest, therefore, that the

mechanism by which adenosine analogues inhibit presynaptic neuronal activity involves inhibition of adenylate cyclase. Furthermore, stimulation of adenylate cyclase by (-)PIA in PTX-treated cells may be responsible for the observed enhancement of transmitter release. Previous studies have suggested that selective A₂ receptor activation and augmented cyclic AMP levels enhance transmitter release^{5,15}.

The ionic mechanism associated with inhibition of synaptic activity by adenosine analogues acting at A₁ receptors remains a matter for speculation. Adenosine analogues have been found to inhibit synaptosomal ⁴⁵Ca fluxes¹⁶, whereas in an electrophysiological study they had no apparent effect on voltage-sensitive Ca²⁺ currents in hippocampal CA1 cells¹⁷. However, in neuroblastoma¹⁸ and rat dorsal root ganglion cells¹⁹, Ca²⁺ currents were potentially inhibited by adenosine analogues. It is possible that different mechanisms exist for pre- and postsynaptic effects of A₁ receptor stimulation.

In several systems PTX has been used to distinguish between receptors which are negatively coupled to adenylate cyclase, and those which are termed calcium-mobilizing, on which PTX had no effect^{20,21}. However, in mast cells PTX has been reported to block the secretory process by preventing activation of calcium-mobilizing receptors²². As neither A₁ nor A₂ adenosine receptors have been classified in this way²³, and as in the present study PTX enhanced rather than inhibited transmitter release, it is unlikely that it acts on calcium-mobilizing receptors. Thus, the results presented here provide clear evidence for the involvement of the N_i protein in the inhibitory effect of A₁ receptor stimulation on transmitter release; it can thus be classed in the same functional group of presynaptic neuronal receptors as enkephalin and α₂ receptors²⁴.

This work was supported by the MRC. We thank Bob Russell and Eric Archer for technical assistance, Drs L. Irons and A. Robinson (PHLS-CAMR, Porton Down, UK) for providing the pertussis toxin, and Dr B. Pearce for the perfusion chamber. **Note added in proof:** In recent experiments we have found (-)PIA (0.5–5 μM) to have no effect on either basal or K⁺-stimulated accumulation of inositol mono-, bis- or trisphosphates, in cerebellar neurones in culture, supporting our contention that (-)PIA acts by inhibition of adenylate cyclase.

Activated human eosinophils generate SRS-A leukotrienes following IgG-dependent stimulation

R. J. Shaw, G. M. Walsh, O. Cromwell, R. Moqbel, C. J. F. Spry* & A. B. Kay†

Department of Allergy and Clinical Immunology, Cardiothoracic Institute, Brompton Hospital, London SW3 6HP, UK
* Department of Immunology, Royal Postgraduate Medical School, Hammersmith Hospital, London W12 0HS, UK

Eosinophils, a class of granular leukocytes, are prominent in many inflammatory processes, particularly in asthma, certain allergic diseases and during infections with helminthic parasites. Following incubation with the Ca ionophore A23187 (refs 1–4) (a non-physiological agent which circumvents membrane calcium-gating mechanisms⁵), eosinophils generate large amounts of sulphidopeptide leukotrienes, potent inducers of smooth muscle constriction^{6–9} and mucus production¹⁰. These are now known to represent the activity previously termed 'slow-reacting substance of anaphylaxis' (SRS-A) but attempts to identify a physiological stimulus for SRS-A production by eosinophils have so far been unsuccessful. The cells contain recognized receptors for IgG (Fc)^{11–14} and it is known that they adhere to, and can be activated by, contact with the surface of large organisms such as helminthic larvae¹⁵. We show here that eosinophils, particularly when activated, produce sulphidopeptide leukotrienes after contact with large particles coated with IgG.

We found that normal eosinophils generated appreciable amounts of SRS-A leukotrienes when incubated with IgG-coated particles, and that this was enhanced twofold when cells were stimulated *in vitro* (by the bacterial analogue f-Met-Leu-Phe (fMLP)) and up to 10-fold when activated low-density cells (from patients with hypereosinophilia) were studied.

Evidence for a harmful role for eosinophils in asthma is

provided by the observation that one of the granular constituents, major basic protein, is released onto and damages bronchial epithelium^{16–19}. On the other hand, this mechanism might give the eosinophil a protective function in adaptive immunity to certain parasitic diseases^{20,21}.

A23187-dependent eosinophil generation of sulphidopeptide leukotrienes (LTC₄, LTD₄, LTE₄)^{1–4} provides a theoretical mechanism by which eosinophils could contribute to the immediate asthmatic reaction. However, the physiological relevance of this observation has remained uncertain because of the artificial nature of the stimulus. Despite evidence of generation of leukotrienes from other circulating cell types using more pathophysiological agents (that is, LTB₄ from neutrophils by opsonized zymosan²², LTB₄ and LTC₄ from mononuclear cells by unopsonized zymosan²³ and LTC₄ from alveolar macrophages by IgE complexes²⁴), no comparable trigger for eosinophil sulphidopeptide leukotriene generation has been identified.

Eosinophils from patients with hypereosinophilia have an increased capacity to kill helminths²⁵. Many of these cells are hypogranular and have reduced density^{26–28}. These low-density cells have altered oxidative metabolism^{29,30}, an enhanced capacity to kill schistosomula of *Schistosoma mansoni* *in vitro*³¹ and increased expression of IgE (Fc) receptors^{32,33}. In addition, low-density eosinophils have an altered expression of cell-surface antigenic determinants³⁴ and are thought to be a sub-population of 'activated' cells.

In the present study IgG-coated Sepharose beads, which are 5–10 times larger than eosinophils (50–100 μm in diameter compared with 14 μm), were used as a stimulant, and the capacity of low-density and normal-density eosinophils to generate sulphidopeptide leukotrienes was examined. Incubation of normal-density eosinophils with IgG-coated beads resulted in a time-dependent release of these leukotrienes (Fig. 1b) related to the amount of adherent IgG (Fig. 1a) and not found with beads coated with human albumin. Furthermore, leukotriene generation by eosinophils in the presence of IgG-coated beads was significantly enhanced by prior incubation with fMLP (10⁻⁸ M) for 30 min (*P* < 0.02) (Fig. 1a, b). Incubation with fMLP in the

Fig. 2 Immunoreactive LTC₄ in the reverse-phase HPLC fractions of the eosinophil products from incubation of: *a*, low-density cells with IgG-coated beads; *b*, low-density cells with albumin-coated beads; *c*, normal-density cells with IgG-coated beads; *d*, normal-density cells with albumin-coated beads (mean $\pm$ s.e.m., $n=3$), were compared with the retention times of synthetic standards.

Methods. Immunoreactive LTC₄ in the reverse-phase (RP) HPLC fractions of supernatants from eosinophils incubated with IgG-coated beads. Eosinophils (10^6 ml^{-1}) were incubated with protein-coated beads as described in Fig. 1 legend. The leukotrienes in the supernatant were extracted in 80% methanol which was diluted to 10% with water and acidified to pH 4 before further extraction using a C18 Sep-Pak (Waters Associates)^{3,44}. The leukotrienes eluting in 100% methanol were evaporated to dryness, resuspended in running buffer (methanol/water/acetic acid, 70:30:0.1, adjusted to pH 5.4 with ammonia) and separated by RP-HPLC on a Nucleosil C18 column. The fractions were evaporated to dryness and resuspended before radioimmunoassay.

Fig. 1 *a*, Generation of LTC₄ by eosinophils in response to incubation with varying numbers of IgG-coated Sepharose beads with or without prior incubation with fMLP. Normal-density eosinophils (10^6 ml^{-1} , >90% purity) were incubated for 30 min with fMLP (10^{-8} M) (●) or buffer (○) followed by 30 min with varying numbers of IgG-coated beads (2.75 mg IgG per 5×10^5 beads) or albumin-coated beads (2.9 mg albumin per 5×10^5 beads) (mean $\pm$ s.e.m., $n=4$). Inset, effect of fMLP on LTC₄ generation by eosinophils incubated with IgG-coated beads. Normal-density cells (10^6 ml^{-1} , >90% purity) were incubated with fMLP or buffer for 30 min followed by 30 min with Sepharose beads ($5 \times 10^5 \text{ ml}^{-1}$) coated with varying doses of IgG or albumin. ●, fMLP + IgG-coated beads; ○, buffer + IgG-coated beads; ■, fMLP + albumin-coated beads; □, buffer + albumin-coated beads (mean $\pm$ s.e.m., $n=8$, * $P<0.05$, ** $P<0.02$). *b*, Time course of release of LTC₄ by eosinophils incubated with IgG-coated beads with enhancement by fMLP. Normal-density eosinophils (10^6 ml^{-1} , >90% purity) were incubated for 30 min with fMLP (10^{-8} M) or buffer, followed by addition of either IgG- (2.75 mg ml^{-1}) or albumin- (2.9 mg ml^{-1}) coated beads ($5 \times 10^5 \text{ ml}^{-1}$) and the incubation terminated after varying time intervals. Symbols, ●, fMLP + IgG-coated beads; ○, buffer and IgG-coated beads; ■, fMLP + albumin-coated beads; or □, buffer + albumin-coated beads (mean $\pm$ s.e.m., $n=4$).

Methods. Human eosinophils were purified on discontinuous metrizamide gradients⁴¹. Populations were identified on the basis of density, normal density (>1.12 g ml^{-1}) in fractions 4 and 5 and low-density cells (<1.12 g ml^{-1}) in fractions 2 and 3. The eosinophils (10^6 ml^{-1}) were incubated with either fMLP (10^{-8}) or buffer at 37 °C for 30 min. The cells were further incubated with human IgG- or human albumin-coated beads, which were left to sediment during the course of the incubation. Beads were prepared with cyanogen bromide-activated Sepharose 4B particles (Pharmacia). These particles were swollen in 1 mM HCl and washed with coupling buffer (0.2 M NaHCO₃ pH 8.7 containing 0.5 M NaCl). Aliquots (1 ml) of gel were incubated with 10, 7.5, 5 and 2.5 mg of human IgG or albumin (Sigma), dissolved in coupling buffer, for 2 h at room temperature with continuous mixing. The purity of the IgG preparation was determined by crossed immunoelectrophoresis (kindly performed by Dr Joan Longbottom). The preparation contained >98% IgG, with albumin and pre-albumin the principal contaminants. There was <0.001% IgE as assessed by a double-antibody radioimmunoassay⁴² (kindly performed by Dr T. G. Merrett). Any remaining reactive groups on the Sepharose were blocked by incubating particles with 1 M ethanolamine pH 8.0 for 2 h at room temperature with frequent mixing. The particles were washed alternately with coupling buffer and acetate buffer (0.1 M, pH 4.0, containing 0.5 M NaCl) to remove any noncovalently bound protein. This resulted in preparations containing 3.30, 2.75, 2.00 and 1.20 mg IgG per 5×10^5 beads, respectively, determined after alkaline digestion of the coupled beads. The incubation was terminated by centrifugation (8,000g for 1 min) and the supernatant stored at -80 °C before radioimmunoassay. Samples were assayed in duplicate using a specific sulphidopeptide leukotriene radioimmunoassay using antisera raised in rabbits which gave cross-reactivity between LTC₄, LTD₄ and LTE₄ of 100:70:8 (refs 3, 43, 44). Statistical analysis was performed using the Wilcoxon matched-pair signed rank test.

Fig. 3 LTC₄ generation by low-density and normal-density eosinophils incubated with IgG-coated beads with or without fMLP. The eosinophils were collected from four patients with hypereosinophilic syndrome and one with Churg-Strauss hyper-eosinophilia (patient 5). The cells were separated on metrizamide gradients into low density (metrizamide fractions 2 and 3, density <1.12 g ml⁻¹) and normal density (metrizamide fractions 4 and 5, density >1.12 g ml⁻¹). The cellular constituents of the low-density fraction from each of the patients were: patient 1, 67% eosinophils (E), 30% neutrophils (N), 30% mononuclear cells (M); patient 2, E, 38%; N, 54%; M, 8%; patient 3, E, 90%; N, 10%; M, 0%; patient 4, E, 54%; N, 46%; M, 0%; patient 5, E, 92%; N, 0%; M, 8%. The cellular constituents of fractions 4 and 5 were: patient 1, E, 95%; N, 5%; patient 2, E, 90%; N, 10%; patient 3, E, 94%; N, 6%; patient 4, E, 95%; N, 5%; patient 5, E, 91%; N, 9%. LTC₄ concentrations (mean $\pm$ s.e.m., $n=5$) were measured after incubating the low-density and normal-density eosinophils (10^6 ml⁻¹) for 30 min with fMLP (10^{-8} M) followed by IgG-coated (black columns) or albumin-coated (white columns) beads (5×10^5 ml⁻¹) at protein concentrations as shown (± 0.1 mg).

presence of albumin-coated beads was not associated with leukotriene generation. The leukotriene production by eosinophils was dependent on the number of beads present, with a maximal eosinophil-to-bead ratio of 2:1 (Fig. 1a).

The identities of the sulphidopeptide leukotrienes produced at 30 min by both normal- and low-density cells were confirmed by comparing immunoreactivity of the fractions with the retention times of synthetic markers using reverse-phase HPLC (Fig. 2). Both cell types generated LTC₄ following incubation with IgG-coated beads. A small amount of activity was present in fractions co-eluting with synthetic LTD₄, indicating partial degradation of LTC₄ to LTD₄. No sulphidopeptide leukotriene immunoreactivity was identified in the products of eosinophils incubated with albumin-coated beads.

LTC₄ generation in the presence of IgG-coated beads by low-density and normal-density eosinophils from five patients with eosinophilia was compared (Fig. 3). In each case the low-density cells generated greater amounts of LTC₄ than the normal-density cells from the same patients over a dose range of IgG. This increased production varied from 1.5 to 10 times that of the normal-density cells and was related to the proportion of eosinophils in metrizamide fractions 2 and 3. Neither normal- nor low-density cells generated LTC₄ when incubated with albumin-coated beads. Production of LTC₄ by low-density cells with IgG-coated beads (16 ng per 10^6 eosinophils) was less than that of normal-density cells treated with Ca ionophore A23187 (41 ng per 10^6 eosinophils)³; only a slight increase in LTC₄ generation was noted following preincubation of low-density cells with fMLP.

Confirmation that the LTC₄ originated from the normal- and low-density eosinophils was obtained by showing that

neutrophils failed to produce LTC₄, and that a mononuclear cell fraction, which also contained basophils (1.2%), generated <1.5 ng LTC₄ per 10^6 cells. We assumed cell viability in all experiments, as leukotrienes are not preformed and their synthesis following stimulation requires energy and is dependent on cell integrity.

The stimulus in this study was IgG (Fc), known to bind to eosinophils by specific Fc receptors¹¹⁻¹⁴. It has been shown previously that fMLP and other chemotactic factors enhance the expression of IgG (Fc) receptors on eosinophils, suggesting that the increased LTC₄ production observed here results from greater stimulus-response coupling^{35,36}. IgG aggregates alone did not consistently trigger LTC₄ generation by eosinophils. On the other hand, the beads provide a large surface similar to that which occurs in helminth cytotoxicity *in vitro*, in which eosinophil secretory activity is stimulated^{15,37}.

The demonstration of LTC₄ generation by activated human eosinophils in response to stimulation with IgG-coated beads may have important implications for human disease. Eosinophils involved in gastrointestinal helminthic infections³⁸ would have access to IgG-coated worms and the resultant leukotriene generation causing mucous hypersecretion and smooth muscle contraction might favour worm expulsion. Similarly, in allergies (where IgG antibodies accompany the IgE response³⁹) eosinophil-derived leukotrienes might amplify the mucus production, bronchospasm, hyperaemia and oedema associated with these conditions. Comparable amounts of LTC₄ have been found in body fluids during allergic reactions (for example, 20 pmol LTC₄ extracted from nasal secretions following allergen challenge⁴⁰).

We thank Dr Penny Fitzharris for helpful discussions. This work was supported by the Wellcome Trust and the MRC.

A group of genes controlling the spatial expression of the bithorax complex in *Drosophila*

Gerd Jürgens

Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft,
Spemannstrasse 37-39, D-7400 Tübingen, FRG

The morphological diversity among the body segments of *Drosophila*, as displayed in the pattern of the larval cuticle¹, arises during embryogenesis by the selective expression of homoeotic genes. For example, the bithorax complex (BX-C) confers abdominal development on the segments in the posterior half of the embryo which otherwise would develop into thoracic segments². Mutations in trans-regulatory genes such as *Polycomb* (*Pc*)³ or *extra sex combs* (*esc*)³ cause indiscriminate expression of the BX-C genes, which leads to all body segments being abdominal. I report here on mutations in four other trans-regulatory genes, members of a novel class of more than 20 genes controlling the spatial expression of BX-C genes. In contrast to *Pc* and *esc* mutations, only partial transformation into posterior abdominal development is observed in mutant embryos. However, embryos mutant for two or more of these genes show strong homoeotic transformation of all body segments similar to, or stronger than, that seen in *Pc* and *esc* embryos, indicating that these genes act synergistically in normal development to control the spatial expression of the BX-C genes.

Recent large-scale screens both for embryonic-lethal mutations affecting the pattern of the larval cuticle⁴⁻⁶ and for dominant 'extra sex combs' mutations (G.J., manuscript in preparation), yielded zygotic mutations in loci other than *Pc* which resemble weak *Pc* mutations in both their dominant adult and recessive embryonic phenotypes. These genes will be collectively referred to as the *Pc* group after its first known and most prominent member. Some of the mutations in the four *Pc* group loci described below were isolated for their embryonic head defect phenotypes, while most of them were identified on the basis of their dominant 'extra sex combs' trait in adult flies. The penetrance of this dominant phenotype depends on culture conditions and genetic background, but the recessive phenotype is embryonic lethality associated with an incomplete transformation of several body segments into more posterior abdominal segments. Three of these genes have not been identified previously, whereas one of them (*Polycomb-like Pcl*) appears to be identical to that described by Duncan⁷ (Table 1).

Mutations at the *Pcl* and *Sex comb on midleg* (*Scm*) loci cause posteriorly directed transformation of abdominal segments in the embryo. In the strongest alleles available, the first abdominal segment resembles the second abdominal segment and abdominal segments 2-7 are transformed into more posterior abdominal segments, while the head and thorax are normal (Fig. 1b). Weaker alleles affect only the more posterior segments, while the weakest *Pcl* allele is homozygous viable and transforms all the legs of adult flies to forelegs, including complete sex combs in males. This phenotype, which resembles the adult phenotype associated with mutations in *Pc* and other putative trans-regulatory genes^{3,7-10}, presumably results from the abnormal expression in the posterior leg disks of the *Sex combs reduced* gene, a member of the *Antennapedia* complex¹¹. Mutations at the *Posterior sex combs* (*Psc*) and *Additional sex combs* (*Asx*) loci represent a different class of phenotype in that they affect the entire body pattern of the embryo. The most prominent feature is a head defect while the posteriorly directed transformation is rather subtle in both head and thorax but clear in the abdomen (Fig. 1c). The incomplete homoeotic transformations associated with the *Pc* group mutations are apparently not the result of incomplete inactivation of these genes as the strongest alleles in *trans* to their corresponding deficiencies (*Pcl*, *Scm*) or the homozygous deficiencies (*Psc*, *Asx*) cause essentially the same phenotypes (Table 1). It should be noted that the lack-of-function phenotypes may be stronger than the amorphic phenotypes described here if these genes were also expressed during oogenesis.

Embryos which are homozygous mutant for any pair of the four *Pc* group loci show strong posteriorly directed transformation of the entire body pattern, resembling the amorphic *Pc* phenotype (Fig. 1d, e). The denticle bands of the trunk segments look very similar to one another and resemble the normal last abdominal denticle band. The head does not undergo involution and two abdominal denticle bands appear there, one ventrally in the gnathal region between the prothorax and the pharynx, and another on the dorsal surface of the head. Although *Pcl* and *Scm* individually appear to affect only the abdomen, the strong transformation seen in double mutant embryos (Fig. 1d) indicates that the *Pcl* and *Scm* gene functions are required for normal development not only in the posterior but also in the anterior half of the embryo.

The embryonic phenotype of the triple mutant *Psc Asx Pcl* is characterized by a tandem array of posterior abdominal segments including up to four abdominal denticle bands in the head region (Fig. 2a). If this transformation were caused by indiscriminate expression of BX-C genes, it should be suppressed in embryos which also lack the BX-C genes as is the

Table 1 Genetic and phenotypic features of *Pc* group genes

Locus	Map position	Cytology*	No. of alleles†	Embryonic phenotype‡
<i>Additional sex combs</i> (<i>Asx</i>)	2-72	51AB	6 (3)	H,T to (A); A1-7 to Ap
<i>Polycomb-like</i> (<i>Pcl</i>)§	2-83	55AF	8 (5)	A1 to (A2); A2-7 to Ap
<i>Posterior sex combs</i> (<i>Psc</i>)	2-67	49EF	1	H,T to (A); A1-7 to Ap
<i>Sex comb on midleg</i> (<i>Scm</i>)	3-49	85EF	4 (2)	A1 to (A2); A2-7 to Ap

* Assignments to polytene chromosome regions are based on the inclusion of the locus in a deficiency: *Asx* in *Df(2)L⁺48*; *Pcl* in *Df(22)PC4*; *Psc* in *Df(2R)vg^D* and *Df(2R)vg^B* but not in *Df(2R)vg^C* (ref. 4); *Scm* in *Df(3R)by¹⁰* and *Df(3R)by⁶²* (ref. 13) but in neither *Df(3R)roe^{XM4}* nor the deficiency segregated by T(2;3)Ctx (ref. 5).

† Two mutants, one *Asx* allele (IIF51) and the *Psc* allele (IIN48), were isolated as embryonic lethal mutations causing head defects⁴. Two *Pcl* alleles (E33 and E90) were isolated as dominant extra sex combs mutations by G. Struhl. One *Asx* allele (P2) was isolated as a dominant enhancer of *Pc* by Dura *et al.*⁸. All other mutants were isolated on the basis of their dominant 'extra sex combs' phenotype in the F₁ male progeny of either ethyl methane sulphonate-treated (50 mM, 24 h) or X-irradiated (4,000 R, 100 kV, 10 mA, 1 mm Al filter, 350 R min⁻¹, Philips MG102) males of one of the following genotypes: *b pr cn sca*, *b pr cn wtx bw*, *st e*, *cp in ri p^P* (ref. 14). Numbers of weak alleles are given in parenthesis. Classification of alleles as either strong or weak is based on the strength of the embryonic phenotype which, however, varies depending on the genetic background. So weak and strong alleles at any of the four loci may show very similar phenotypes, except *Pcl^{XT56}*, which is homozygous viable.

‡ Amorphic or probably amorphic phenotypes: H,T to (A), abdominal denticles in head and thorax; A1 to (A2), incomplete transformation of abdominal segment 1 into segment 2; A1-7 or A2-7 to Ap, abdominal segments 1-7 or 2-7 transformed to more posterior segments, often in a graded fashion with segments 5-7 closely resembling A8.

§ *Pcl* is probably identical to the *Pcl* locus described by Duncan⁷ as judged by map position, cytology and similarity of phenotype.

|| Chao-ting Wu (personal communication) has found that alleles of *Suppressor of zeste-2* do not complement the lethality of *Psc^{IIN48}*. However, the three alleles 1, 4 and 5 of *Su(z)2* do not share the embryonic phenotype of *Psc^{IIN48}* and *vg^D* (unpublished data) so the allelic relationship between *Psc* and *Su(z)2* should be considered unclear.

Fig. 2 Comparison between *Psc Asx Pcl* (a), *Psc Asx Pcl;P9* (b) and *P9* (c) embryos. *P9* deletes the entire BX-C^{2,16}, causing thoracic transformation of abdominal denticle bands and resulting in the presence of chitinous structures posterior to transformed segment A8^{2,17}. a, Extreme transformation of all body segments towards A8. Abdominal denticle bands appear in the head region at four different levels, one on the dorsal surface, one anterior and two posterior to the floor of the pharynx (asterisks). Head involution is blocked so the remnants of head structures remain on the outside. b, Suppression of abdominal features. Instead, mesothoracic denticles appear on the dorsal surface of the head (asterisks) and in trunk segments T1 to A8. Note the supernumerary A9 which bears prothoracic denticles (arrowhead) and the presence of chitinous plates in most body segments (arrows) which indicate transformation towards head structures (compare posterior end of *P9* embryo). c, Segments T2 to A7 show mesothoracic denticle bands, while the denticle band of A8 appears to be intermediate between normal T1 and T2. Note the presence of Keilin's organs (arrows) and black dots (arrowheads) in all trunk segments and the presence of chitinous plates posterior to A8 (asterisks). Dorsally, the segments T2 to A8 appear to be composed of anterior T2 and posterior T1, and a ninth abdominal segment is recognizable between the chitinous plates (asterisks) and the tuft. ap, Anal plate; as, anal sense organ; mx, maxillary sense organ; sp, posterior spiracles; tf, tuft. Other abbreviations as for Fig. 1.

expressed *Pc* group genes suggests a surprising complexity of the *trans*-regulatory system that controls the spatial expression of homeotic genes. It is conceivable that such a complex system is better buffered against perturbation and thus better adapted in evolutionary terms than would be a spatial control by only one or a few *trans*-regulatory genes. If one were to view segment diversity as the result of evolutionary modification of a single repeated pattern¹², slight genetic changes in *trans*-regulatory genes controlling the spatial expression of homeotic genes might gradually have built up the necessary genetic isolation between segments to ensure largely independent evolution of segment-specific features.

Much of the work reported here was done in the laboratory of C. Nüsslein-Volhard and E. Wieschaus at the EMBL, Heidelberg, while G.J. was holding an EMBO long-term fellowship. G.J. thanks G. Struhl and P. Santamaria for supplying mutant stocks, Chao-ting Wu for sending her *Su(z)2* alleles and unpublished information, C. Nüsslein-Volhard, K. V. Anderson, R. Lehmann and H. G. Frohnhofer for critical comments, H. Jäckle and S. Goodman for critically reading the manuscript, R.

Groemke-Lutz for photographic prints, and A. Beermann for help with the figures.

Local degradation of fibronectin at sites of expression of the transforming gene product pp60^{src}

Wen-Tien Chen*, Jinq-May Chen*, Sarah J. Parsons† & J. Thomas Parsons†

* Department of Anatomy, Georgetown University, Schools of Medicine and Dentistry, Washington, DC 20007, USA

† Department of Microbiology, University of Virginia, School of Medicine, Charlottesville, Virginia 22908, USA

Local degradation of extracellular fibronectin, a major extracellular adhesive protein, is believed to play an important part in the migration of cells through the extracellular matrix during tumour invasion, morphogenetic movement and trophoblast implantation¹⁻⁵. Fibronectin is lost from the cell surface after transformation with Rous sarcoma virus (RSV)⁶. By using fluorescent and radiolabelled probes covalently coupled to the surface of substrata, we have recently identified a proteolytic activity that is expressed in RSV-transformed cells and is involved in the local degradation of fibronectin at cell-substratum contact sites⁷. Here, we extend the relevance of these findings and gain some insight into the cellular functions of pp60^{src}, the transforming gene product of RSV. We show that newly expressed viral pp60^{src} is localized at the cytoplasmic surface of the cell membrane, corresponding to the cell contact sites where degradation of extracellular fibronectin occurs.

Localized fibronectin degradation was detected in cells cultured on fixed gelatin films coupled with rhodamine- or radio-labelled fibronectin in the presence of 10% fetal bovine serum. The appearance of black spots on the uniformly fluorescent surface of the gelatin film indicated sites of local fibronectin degradation. The resulting release of labelled fibronectin into the medium provided a measure of the cleavage of the polypep-

tides by the cells⁷. Because there was an induction of rosette contacts on RSV transformation of cells concomitant with a redistribution of α -actinin and vinculin to rosette contacts⁷⁻¹¹, we used monoclonal antibody N.353 directed against α -actinin for immunolabelling of the rosettes in the transformed cells in the above preparation, in order to determine whether the local degradation of fibronectin occurs at rosettes.

The system chosen for the study of cell transformation consisted of primary cultures of chicken embryo fibroblasts (CEF) infected with a temperature-sensitive mutant (ts68) of RSV¹². Infected cells exhibited the transformed phenotype when grown at the permissive temperature (37 °C) after a shift from the non-permissive temperature (41 °C). ts68-CEF grown at the permissive temperature for various times therefore allow a direct analysis of the transformed phenotype. Figure 1 shows that within 1 h after the temperature shift (Fig. 1a-c), a few black spots appeared on the rhodamine-fibronectin substrata (Fig. 1b) and these coincided with the immunoreactive α -actinin-rich rosette contacts of transformed cells (Fig. 1c). However, within 6 h after the shift (Fig. 1d-f), the cells became rounded, a morphological change that was accompanied by increasing numbers of degraded fibronectin spots (Fig. 1e) coinciding with α -actinin-rich rosette contacts (Fig. 1f). As shown previously in RSV-transformed cells⁷, the degraded spots appear at the rosettes (Fig. 1, open arrows), but never at the focal adhesions (Fig. 1, fluorescent streaks). In addition, the pattern of degraded spots is distinct from that of fibronectin displacement from non-coupled substrata exhibited by normal or transformed cells⁷. Furthermore, the initial release of radioactivity from the fibronectin substrata was detectable by 6 h after the temperature shift in ts68-CEF cultures (result not shown). The released material was characterized as peptides of relative molecular mass (M_r) < 30,000. Thus, localized degradation of extracellular fibronectin occurs at sites of rosette contacts of RSV-transformed cells.

Previous efforts to localize pp60^{src} all involved the use of polyclonal antisera^{9,10,13-15}. Because these antisera react with both cellular and newly expressed viral pp60^{src}, we examined

Fig. 1 Demonstration of the time course of expression of a transformation-associated protease that degrades fibronectin at rosette contact sites. ts68-infected CEF were grown at the permissive temperature (37 °C) for 1 h (a-c) and 6 h (d-f) after a temperature shift from 41 °C. a, d, Differential interference contrast images of the cells. b, e, Fluorescent images of rhodamine-labelled fibronectin substrata showing fields of the same cells as in a and d, respectively. Black spots (open arrowheads) represent areas where fibronectin has been locally degraded. c, f, Immunofluorescence images of the same cells as in a and d, respectively, using indirect monoclonal antibody labelling for intracellular α -actinin. α -Actinin is redistributed on transformation to rosette sites (open arrowheads) which coincide with the black spots in b and e.

Methods. The ts68-infected CEF were cultured in Dulbecco's modified Eagle's medium containing 10% fetal bovine serum on rhodamine conjugates of fibronectin that were covalently linked to the surface of a fixed gelatin film¹⁷. The cultures were then shifted to the permissive temperature (37 °C) for various periods of time before fixation and permeabilizing with 0.5% Triton X-100 for antibody labelling. The fixed cells were labelled indirectly, first with mouse monoclonal antibody N.353 directed against α -actinin (Amersham Corp., Arlington Heights, Illinois), then with fluorescein conjugates of goat antibody to mouse IgG and IgM. Labelled cells were observed with a Zeiss Photomicroscope III equipped with epifluorescence and a Planapo 63/1.4 objective. Scale bar, 10 μ m.

Fig. 2 Coincidental localization of viral pp60^{src} and fibronectin degradation at sites of rosette contacts. Normal CEF (*i, j*) and ts68-infected cells were grown either at the non-permissive temperature (41 °C) (*g, h*), or at the permissive temperature (37 °C) for 1 h (*a-c*) and 6 h (*d-f*) after a temperature shift from 41 °C. The ts68 RSV-transformed cells were cultured on rhodamine-fibronectin substrata according to the procedure described in Fig. 1 legend, except that fixed cells were indirectly labelled with EB7 directed against an epitope of viral pp60^{src}. *a, d*, Immunofluorescence images of transformed cells labelled with EB7 for localization of intracellular viral pp60^{src}. Open arrowheads indicate rosette contacts that appear after cell transformation. White arrowheads point to focal adhesions, which are commonly found in both normal and transformed cells. *b, e*, The rhodamine-fibronectin substrata under the cells shown in *a* and *d*, respectively. Black spots represent sites of local fibronectin degradation, and are present at areas corresponding to rosette contacts (open arrowheads), but absent at focal adhesion (solid arrowheads) and areas free of cell contact. *c, f*, Overlay tracing of pp60^{src} localization in the cells of *a* and *d* (dotted outline) and of degraded fibronectin spots on substrata of the same fields (solid areas). *g, h*, Viral pp60^{src} labelling of ts68-CEF grown at 41 °C (*g*) and its underlying labelled fibronectin substrata (*h*). *i, j*, Control for viral pp60^{src} labelling in normal CEF (*i*) and the corresponding labelled fibronectin substrata (*j*). The same exposure time was used for photographing the viral pp60^{src} labellings in all preparations. Scale bar, 10 µm.

the intracellular localization of viral pp60^{src} by using monoclonal antibody EB7, which recognized an epitope in the amino-terminal region (residues 1-82) of the viral pp60^{src}, but did not efficiently recognize determinants on the cellular pp60^{src} homologue^{16,17}. To determine whether local removal of fibronectin also occurs at the sites of expression of viral pp60^{src} on RSV transformation, ts68-CEF were grown on rhodamine-fibronectin substrata at the non-permissive temperature (41 °C), shifted to 37 °C for various periods of time as described above, then immunolabelled with EB7 to compare the time-course correlation between viral pp60^{src} localization and the sites of fibronectin degradation. In normal CEF grown at 41 °C or 37 °C, we observed neither viral pp60^{src} labelling nor degraded spots (Fig. 2*i, j*). In ts68-CEF grown at 41 °C, viral pp60^{src} labelling was diffuse in the cytoplasm, but no local fibronectin degradation was detected (Fig. 2*g, h*). Within 1 h after the temperature shift to 37 °C, viral pp60^{src} was localized at both focal adhesions and rosette contacts (Fig. 2*a, c*), but mostly within rosettes at later times (Fig. 2*d, f*). Concomitantly, local fibronectin degradation was found mostly at rosettes, but not at focal adhesions (Fig. 2*b, c, e, f*). As shown in Fig. 1, however, there is not a perfect one-to-one correspondence between pp60^{src} and spots of fibronectin degradation, indicating that some of the rosettes either show little proteolytic activity or have become detached from the original sites. These results suggest a temporal and spatial relationship between rosette formation, local fibronectin degradation and viral pp60^{src} expression in RSV-transformed cells. It appears that viral pp60^{src} is produced in cells at the non-permissive temperature and becomes accumulated in functional sites at rosettes after the shift to the permissive temperature.

Functional expression of pp60^{src} is required for manifestation of the oncogenic events which are initiated on RSV infection^{12,18}.

Several studies have shown that viral pp60^{src} has the following characteristics: (1) it has an intrinsic tyrosine-specific phosphotransferase activity^{19,20}; (2) it is localized on the cytoplasmic face of the plasma membrane²¹; (3) its target proteins include the adhesion plaque component vinculin¹³; and (4) it has a cellular homologue²², which has been identified recently. The common localization for viral pp60^{src} and fibronectin degradation at rosette contacts demonstrated here suggests membrane-associated sites of action for both pp60^{src} and the extracellular protease. The pp60^{src} kinase may exert its primary effects on the plasma membrane at the rosettes through phosphorylation of integral membrane components²³ or of cytoplasmic vinculin^{9,13}. Such modification may directly or indirectly induce protease activity on the rosettes and thereby cause the local dissolution of fibronectin from the extracellular matrix. Such an effect could in turn have an important role in the local decrease in cell-substratum adhesion, in the rounding-up of the cell, and in the disorganization of the stress fibres that accompanies transformation of fibroblasts by RSV.

Overproduction of p53 antigen makes established cells highly tumorigenic

D. Eliyahu, D. Michalovitz & M. Oren

Department of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel

The p53 cellular tumour antigen, long known to be overproduced in a variety of neoplastically transformed cells^{1,2}, was recently shown to be directly involved in transformation. Thus, p53 can complement activated Ha-ras in transforming secondary rat embryo fibroblasts into grossly altered, tumorigenic cells^{3,4}. Moreover, p53 can also be shown to possess immortalizing activity⁵. Our previous results indicated, however, that the contribution of p53 to the transformation was not synonymous with immortalization, suggesting that the two activities of the protein are probably separable⁶. We demonstrate here that this is indeed the case, as overproduction of p53 in an established cell line, while not causing gross morphological changes, endows these cells with an overt tumorigenic potential. Furthermore, the tumorigenic efficiency of such cell lines may be correlated with the extent of p53 overproduction.

Co-transfection of rat embryo fibroblasts with a combination of activated Ha-ras and transcriptionally-potentiated p53 effectively generates morphologically transformed cells, capable of overgrowing the growth-arrested monolayer of normal cells^{3,4}. However, only a small fraction of such transformed cells are capable of continuous growth³. It was therefore proposed that

Fig. 1 Map of plasmid pLTRp53cG. To generate this construct, the DNA of plasmid pSVp53cG3 (ref. 12) was cleaved with *EcoRI* and *BglII* to remove simian virus 40 (SV40) sequences and then treated with the Klenow fragment of *Escherichia coli* DNA polymerase I to generate blunt ends. In parallel, a cloned proviral Harvey murine sarcoma virus (clone H-1; ref. 13), was cleaved with *SmaI*. The 1.3-kilobase fragment containing the retroviral 5'LTR (long terminal repeat) was isolated and introduced into the above blunt-ended vector. The resultant plasmid, pLTRp53cG, contains the LTR-derived enhancer, promoter and cap sites¹⁴, followed by a chimera of p53-specific DNA and genomic DNA¹². Solid bar, LTR sequences and adjacent 5' flanking cellular sequences; open bar, p53-specific sequences; thin line, pBR322 DNA; hatched bar, SV40 DNA. although nuclear oncogene products may have immortalizing potential, as was later in fact demonstrated for p53⁵, their ability to participate in neoplastic transformation may reflect an entirely different facet of their activity³. If this were the case, one might anticipate that certain types of established, non-transformed cells could be converted into more neoplastic ones by the mere overproduction of p53.

To test this assumption, we attempted to generate cell lines which over-produced the p53 antigen. Rat-1 cells⁶ were co-transfected with a mouse p53-specific expression vector together with a dominant selectable marker, ptkgpt (given by M. Shani). In the present study, we used a construct containing a chimera of p53 complementary DNA and genomic DNA (pLTRp53cG; Fig. 1). Rat rather than mouse cells were chosen because the p53 proteins of the two species can be easily differentiated with the aid of specific monoclonal antibodies, thus ruling out the possibility of endogenous rat p53 being nonspecifically induced by irrelevant parts of the transfecting plasmids. Mycophenolic-acid-resistant colonies were isolated⁷, expanded and analysed for the expression of mouse p53. Of 24 clones tested, most expressed little or no detectable murine p53. Only two lines displayed a very prominent overproduction of mouse p53, while two others made more moderate amounts of this protein. Figure 2 depicts the analysis of several such cell lines, using either a

Fig. 2 Detection of p53 in Rat-1-derived cell lines. Cells were grown in 60-mm dishes and labelled with 30 μ Ci ³⁵S-methionine per dish for 4 h. Proteins were extracted, immunoprecipitated and analysed by SDS-polyacrylamide gel electrophoresis as described previously⁸. Immunoprecipitation was with either monoclonal antibody RA3-2C2, specific for mouse p53¹⁵ (a), control serum (b, lanes labelled C) or monoclonal antibody pAb421, (L21)¹⁶, recognizing both mouse and rat p53¹⁵ (b, lanes I). Rat-1 is the parental cell line used for transfections; clone 26 is derived from rat embryo fibroblasts transformed by p53 plus Ha-ras³; all other cell lines were generated by co-transfection of Rat-1 cells with a p53-specific expression plasmid and ptkgpt. Each lane represents the polypeptides precipitated from 1.8×10^6 trichloroacetic acid-insoluble c.p.m. p53r and p53m denote the positions of rat and mouse p53, respectively. Numbers to the left of b refer to the relative molecular mass ($\times 10^{-3}$) of co-electrophoresed markers.

Fig. 3 Morphology of Rat-1-derived cells (phase-contrast photomicrographs). *a*, Parental Rat-1 cells; *b*, IB2; *c*, IIIC6; *d*, IIB4; *e*, IIB4T, a cell line established from a tumour induced in a nude mouse by injection of IIB4 cells. $\times 83$.

mouse p53-specific antibody (Fig. 2) or one reactive with both the mouse and rat species (*b*). In two lines (IIB4 and IIIC6), the production of mouse p53 well exceeds that of clone 26, a tumorigenic cell line derived by co-transfection of rat embryo fibroblasts with p53 plus Ha-ras (ref. 3 and D.E. *et al.* in preparation).

Unlike the case for p53 plus Ha-ras co-transformants, the p53-overproducing Rat-1 cells exhibited no dramatic morphological changes (Fig. 3). Some cell lines, such as IIB4, possessed a slightly altered shape while others, such as IIIC6, were practically indistinguishable from the parental Rat-1.

Overproduction of p53 can sometimes be due to post-translational events^{8,9}. Hence, it was of interest to determine whether the augmented levels of the protein in these cell lines reflected, as expected, the presence of larger amounts of the corresponding messenger RNA. Total cytoplasmic RNA was prepared from several lines and analysed directly by electrophoresis on a denaturing gel and hybridization with a mouse p53 cDNA probe. Both IIB4 and IIIC6, marked producers of the protein, contain conspicuous quantities of p53 mRNA (Fig. 4).

To test whether p53 overproduction could alter the biological properties of established cells, representative cell lines were injected into nude mice and monitored for the appearance of tumours. The results, summarized in Table 1, clearly demonstrate that both p53-overexpressing lines are highly tumorigenic, clone IIB4 being more efficient than IIIC6. Since IIB4 appears

Fig. 4 Detection of p53-specific transcripts in various cell lines and in a tumour. Total cytoplasmic RNA was extracted from several cell lines (first five lanes) by the Nonidet-P40 method¹⁷. In parallel, total cellular RNA was prepared from a tumour induced in a nude mouse by the injection of IIB4 cells (lane IIB4T) using the guanidine thiocyanate procedure¹⁸. RNA (8 μ g) was electrophoresed through a formaldehyde agarose gel¹⁹, blotted onto nitrocellulose²⁰ and hybridized with the 950-base pair p53-specific cDNA insert of clone pp53-176 (ref. 21) as described previously²².

Table 1 Tumorigenicity of Rat-1-derived cell lines in nude mice

Cell line	Mouse p53	2 Weeks		4 Weeks		8 Weeks	
		Score	Size	Score	Size	Score	Size
Rat-1	—	0/4	—	0/4	—	1/4	4
IIIC2	—	0/2	—	0/2	—	ND	
IIIC6	++	0/5	—	4/5	3–5	5/5	3–12
IIB4	+++	8/11	4–7	11/11	8–20		

CD1 *nu/nu* mice were injected subcutaneously with 5×10^6 cells. The numbers and sizes of resultant tumours were monitored for 8 weeks after injection. Score values indicate the number of tumour-bearing mice over the total number of animals injected with the particular cell line. Also shown is the range of sizes (in mm) of the observed tumours. ND, not determined.

to make more p53 than IIIC6, as determined by radiolabelling (Fig. 2), it is possible that the extent of p53-overexpression may determine the tumorigenic potency of these cells. It should be noted that a small tumour became visible after 8 weeks in one mouse injected with parental Rat-1 cells; this is in accord with the previously described ability of these cells to cause tumours with a long latency⁶. Thus, p53 may be markedly enhancing a latent tumorigenic potential of established cells rather than conferring such a potential *de novo*.

The rapid rate of tumour appearance following injection of IIB4 cells suggests strongly that their tumorigenicity is a property of the whole population rather than of a minor subset of different, fully transformed cells. Nevertheless, it was desirable to determine whether the cells comprising the tumour were not fundamentally different from those initially injected. To that end, we first determined the level of p53 mRNA in the tumour. The result (Fig. 4, lane IIB4T) clearly indicates that the tumour still makes very large quantities of p53 mRNA of the expected size; there is also a band of high relative molecular mass, not seen in tissue-cultured IIB4 cells. As the tumour RNA was extracted by a procedure which still retains the nuclear fraction, this higher band probably represents a precursor accumulating to high levels in the nuclei.

To further characterize such tumours, we excised one of them and placed it in tissue culture. The resultant cell line, IIB4T, had a morphology completely indistinguishable from that of the

parental IIB4 line (Fig. 3). This is in marked contrast to the results of a similar analysis on tumorigenic lines derived from p53 plus Ha-ras transformants (D.E. *et al.*, in preparation). Finally, protein analysis revealed that IIB4T possess the same level of p53 as IIB4 (data not shown), suggesting that the cells constituting the tumour are identical to those initially injected.

The data presented here argue strongly that the mere overproduction of p53 is sufficient to cause established cell lines to become tumorigenic. While this work was in progress, essentially similar findings were reported for the *myc* oncogene¹⁰, which also has several other properties in common with p53 (refs 3, 4, 11). As the immortalizing capacity of these nuclear oncogene products is irrelevant for established cell lines, one must conclude that both genes possess additional biological activities which are directly involved in tumour formation, while having no discernible effect on the apparently normal morphology of the cells. Whether these additional activities are the same for p53 and *myc* remains to be determined.

Human N-myc gene contributes to neoplastic transformation of mammalian cells in culture

Manfred Schwab*†, Harold E. Varmus† & J. Michael Bishop*†

*The G. W. Hooper Foundation and †Department of Microbiology and Immunology, University of California, School of Medicine, San Francisco, California 94143, USA

Proto-oncogenes represent a group of eukaryotic genes whose activated forms are implicated in the development of cancer (for reviews, see refs 1-3). We have recently identified a human gene, *N-myc*, that is distantly related to the proto-oncogene *c-myc*⁴. *N-myc* is expressed at abnormally high levels consequent to amplification in numerous human neuroblastoma cell lines and metastatic neuroblastoma tumours^{5,6}. In addition, enhanced expression of *N-myc*, often a result of amplification, has been found in retinoblastoma cell lines and tumours (refs 5, 7 and M.S., unpublished data) and in cell lines derived from small-cell car-

Fig. 1 Molecular clones of *N-myc*. *a*, Partial restriction endonuclease maps. The clones pNb-9 and pMP-34.1 were used for transfections. H, *Hind*III; R, *Eco*RI; B, *Bam*HI; Bg, *Bgl*II; X, *Xho*I. Heavy lines beneath the map of pNb-9 indicate the domains within which the 5' and 3' ends of *N-myc* must lie. Transcriptional orientation is from left to right. The U3 region in clone pMP-34.1 is derived from a M-MuLV LTR. The *Bam*HI site in the LTR used for attachment to *N-myc* is normally not present, but is the result of insertion of a polylinker in the natural *Kpn*I site within the R region of the Moloney murine leukaemia virus LTR. *b*, Expression of *N-myc* clones in Rat-1 cells. *N-myc* constructs were co-transfected together with a gene conferring resistance against the drug neomycin (molar ratio ~10:1) according to routine procedures¹⁰, and resistant cells were selected using the drug G418 (Gibco; 800 μ g ml⁻¹ crude). Cells were then grown in mass culture, polyadenylated RNA was isolated from a cytoplasmic fraction, and 5 μ g per lane was separated on a 1% agarose gel in the presence of 2.2 M formaldehyde. The RNA was transferred to nitrocellulose paper which was then probed with ³²P-labelled insert of plasmid clone pNb-1 (ref. 4). pNb-101 represents a cosmid clone containing a ~35 kb insert encompassing *N-myc*. NMB represents Kelly, a human neuroblastoma cell line.

cinomas of the lung⁸. Here, we show that enhanced expression of *N-myc* subsequent to co-transfections of an *N-myc* expression vector and the mutant *c-Ha-ras-1*(EJ) (from the human bladder carcinoma cell line EJ) is a factor in tumorigenic conversion of secondary rat embryo cells. The transformed cells elicit tumours in athymic mice and isogeneic rats. The ability of *N-myc* to contribute to neoplastic transformation of cultured mammalian cells raises the possibility that enhanced expression consequent to amplification of *N-myc* may be a factor in the aetiology of human neuroblastoma.

To design a suitable *N-myc* expression vector, we have generated a preliminary definition of the boundaries of *N-myc* in human DNA. We found that *N-myc* is localized within an ~16.0-kilobase (kb) *Hind*III fragment (Fig. 1*a*; clone pNb-9) (M.S. *et al.*, manuscript in preparation). The 5' end of *N-myc* appears to reside within a 1.0-kb *Bam*HI/*Eco*RI fragment; the 3' end maps within a 2.0-kb *Bgl*II/*Eco*RI fragment in close proximity to the *Eco*RI restriction endonuclease site. A DNA fragment containing the U3 region of a long terminal repeat (LTR; clone pMP-1) of Moloney murine leukaemia virus (M-MuLV) was covalently linked to *N-myc* derived from the Kelly neuroblastoma cell line and from a normal individual, to generate clones pMP-34.1^K and pMP-34.1^N, respectively. Rat-1 cells, into which either one of these clones was introduced by transfection of DNA co-precipitated with calcium phosphate⁹, produced high levels of an ~4.0-kb *N-myc* transcript, as do human neuroblastoma cells containing amplified *N-myc* (Fig. 1*b*). *N-myc* messenger RNA was not detected in Rat-1 cells into which

Table 1 Transformation of rat embryo cells

Gene transfected	Clone*	No. of foci†
LTR/N-myc (Kelly) + c-Ha-ras-1 (EJ)	pMP-34.1 ^K + pEJ(6.6)	30-40
LTR/N-myc(normal) + c-Ha-ras-1 (EJ)	pMP-34.1 ^N + pEJ(6.6)	30-40
LTR/N-myc(Kelly; mutant) + c-Ha-ras-1(EJ)	pMP-34.1 ^K ΔXho + pEJ(6.6)	0
N-myc (Kelly) + c-Ha-ras-1 (EJ)	pNb-9 ^K + pEJ(6.6)	0
N-myc (normal) + c-Ha-ras-1 (EJ)	pNb-9 ^N + pEJ(6.6)	0
N-myc (Kelly) + LTR	pNb-9 ^K + pMP-1	0
N-myc (normal) + LTR	pNb-9 ^N + pMP-1	0
c-Ha-ras-1 (EJ) + LTR	pEJ(6.6) + pMP-1	0
LTR/N-myc (Kelly)	pMP 34.1 ^K	0
LTR/N-myc (normal)	pMP 34.1 ^N	0
c-Ha-ras-1	pEJ(6.6)	0
LTR	pMP-1	0

Primary cultures of rat embryo cells (REC) were prepared from 12-14-day-old Fisher rat embryos. After 2-4 days of growth in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum (FCS; Hyclone) and antibiotics, the cells were seeded at a density of 1×10^6 cells per 100-mm dish. Transfections were performed using 75 μ g of carrier DNA from salmon sperm plus roughly equimolar amounts of DNA of the various constructs (6.6 μ g pEJ (6.6); 13 μ g pMP-34.1; 16 μ g pNb-9; 1 μ g pMP-1) for two dishes which at the time of transfection contained 4×10^6 cells. About 24 h after transfection, the cells were split at a ratio of 1:3, re-fed at 3-day intervals with DMEM plus 5% and inspected for focus formation.

* For clones pMP-34.1 and pNb-9 see Fig. 1a. The mutated LTR/N-myc was generated by linearizing clone pMP-34.1^K at the single *Xho*I restriction endonuclease site (Fig. 1a), recutting the protruding single-stranded ends, followed by religation, thus creating a 4-base pair deletion. For clone pEJ (6.6) see ref. 11. Clone pMP-1 contains the U3 region of M-MuLV long terminal repeat (LTR).

† Based on three different experiments each involving $\sim 4 \times 10^6$ cells at the time of transfection.

clones pNb-9^K and pNb-9^N or cosmid clone pNb-101 (map not shown) had been introduced. We observed no obvious morphological differences between untransfected Rat-1 cells and those expressing high levels of human N-myc mRNA.

Previous studies¹⁰ had shown that second-passage rat embryo cells undergo neoplastic transformation when either a viral *myc* gene or a truncated *c-myc* from a murine plasmacytoma cell line, attached to a transcriptional enhancer, is co-transfected with c-Ha-ras-1(EJ). Co-transfection of rat embryo cells with the N-myc expression vectors pMP-34.1^K and pMP-34.1^N (Table 1) and c-Ha-ras(clone pEJ6.6; ref. 11) resulted in formation of foci between 7 and 10 days after transfection at a frequency of ~ 30 -40 foci per 4×10^6 cells. There was no obvious difference in the efficiency of N-myc genes derived from neuroblastoma line Kelly and of those from the normal individual. We did not obtain focus formation with any one of the control clones (Table 1). In particular, focus formation did not occur when we used an N-myc expression vector containing a frameshift mutation within N-myc, showing that enhanced expression of the product encoded by N-myc is required for neoplastic transformation.

Closer inspection revealed two morphologically different types of foci (Fig. 2): type I consisted of disorganized, loosely arranged, small, round to ovoid, refractile cells (Fig. 2a). The cells never reached high density within the focus, but floated off the bottom of the plate. Cells of individual foci grew in a three-dimensional pattern to high density (up to 2×10^8 cells per 100-mm dish (Fig. 2d,f)). Foci of type II consisted of elongated fibroblastic cells which grew in an organized pattern tightly attached to the surface of the plate (Fig. 2c). Individual foci grew into a flat monolayer (density up to 2×10^7 cells per 100-mm dish; Fig. 2e, g). The fraction of type II foci amounted to ~ 10 -20% of the total number of foci. The emergence of two different types of foci following co-transfection of N-myc and c-Ha-ras-1(EJ) cannot be fully explained at present. These different morphologies have not been reported for experiments in which *c-myc* or *v-myc* were used¹⁰. It is possible that different levels of N-myc and/or Ha-ras mRNA account for the different phenotypes of neoplastically transformed cells. Another possibility is that cells of different embryonic lineages present in the second-passage embryo cell cultures assume different phenotypes following uptake of N-myc and c-Ha-ras-1(EJ). Cells of all foci could readily be established as permanent lines, and all cells of individual foci appeared to start growing without delay.

Approximately 10^4 cells of foci of type I, when injected subcutaneously or intraperitoneally into athymic mice and

isogenic rats, formed tumours that caused death within 2-3 weeks. The results were not affected by irradiation of the animals before injection of the cells. Cells of type II foci did not yield tumours even when 5×10^7 cells were injected into X-ray-irradiated animals.

Cells of eight foci selected from two independent transfection experiments all contained 15-30 copies of N-myc and 10-20 copies of c-Ha-ras-1 (data not shown). Cells of all foci contained a major N-myc mRNA of 4.0 kb. The concentration of N-myc mRNA varied considerably among cells derived from different foci but did not correlate with the amount of N-myc DNA. Cells of type I foci generally contained high concentrations of N-myc mRNA (Fig. 3, lines VI-a, -d, -e and -k; VII-b, -c), as much as

Fig. 2 Photomicrographs of rat embryo cells showing normal cells (b), and the morphology of foci of type I (a) and type II (c), resulting from transformation by LTR/N-myc and c-Ha-ras-1 (EJ). d, f, Transformed cells of focus type I (cell line VI-d) at low and high density, respectively. e, g, Cells of focus type II (line VI-j) at low and high density, respectively.

Fig. 3 Expression of *N-myc* and *c-Ha-ras* in rat embryo cells transformed by LTR/*N-myc* and *c-Ha-ras*-1 (EJ). Individual foci of transformed cells were cloned and grown into mass culture. Total polyadenylated RNA was isolated and analysed by agarose gel electrophoresis. VI-a, -d, -e and -k, and VII-c are cells derived from type I foci; VI-j and VII-a are cells from type II foci. REC, rat embryo cells; NMB, human neuroblastoma cell line. Each lane contains ~5 µg of RNA. The probe for *N-myc* was the *Eco*RI/*Bam*HI insert of pNb-1; for *ras*, the *Eco*RI insert of clone BS9 was used¹⁹.

10 times the level found in the neuroblastoma line NMB. Cells of type II foci generally contained lower levels of *N-myc* mRNA (lines VI-j, VII-a) that resembled the levels in neuroblastoma cell line NMB, although the level was in some instances only slightly lower than in type I cells (compare VI-d or -k with VI-j). There was apparently no absolute correlation, however, between the transformed phenotype of the cell and the level of *N-myc* mRNA: the level in the highly tumorigenic line VI-d was only slightly higher than that in the non-tumorigenic line VI-j.

In contrast, there seemed to be a correlation between the level of *Ha-ras* mRNA and the cellular morphology (Fig. 3). Levels of mRNA in cells of type I foci were three to five times higher than in rat embryo cells; in cells of type II foci, the level was not detectably higher than in rat embryo cells. The implications of this correlation are not clear. One possibility being tested is whether *N-myc* is capable of immortalizing rat embryo cells in culture.

N-myc, *c-myc* and *v-myc* apparently contribute in similar ways to transformation of early-passage embryo cells. The fact that at least one neuroblastoma cell line carries amplified *c-myc* instead of amplified *N-myc*¹² and, conversely, that several lines of cells from small-cell carcinoma of the lung have amplified *N-myc* instead of amplified *c-myc*⁷, indicates that there may also be a functional relation between *N-myc* and *c-myc* in the aetiology of naturally occurring tumours. It is not clear, however, that the similarities among the nucleotide sequences of *N-myc*, *c-myc* and *v-myc* are responsible for the apparent functional relationships. The function of *myc* genes in neoplastic transformation of cultured cells apparently can also be assumed by genes whose protein products are related to that of *myc* in regions other than the *N-myc/c-myc* similarity¹³, such as adenovirus early region 1A (ref. 14), or by genes whose relation to *myc* is not clear at present, such as those encoding the polyoma large-T antigen¹⁴ or the cellular tumour antigen, p53¹⁵⁻¹⁷.

We have found previously that enhanced expression and amplification of *N-myc* are correlated with stage III and IV neuroblastomas, characterized by poor prognosis⁸. It is not clear how the biological activity of *N-myc* in cultured cells relates to amplification of the gene in advanced neuroblastomas. The assessment of the role of *N-myc* in human neuroblastoma is complicated by the fact that classification of a specific stage of neuroblastoma is mainly based on the clinical picture at the

time of diagnosis rather than on cellular parameters; moreover, it is not known whether tumours of higher stages develop from lower-stage tumours. The correlation of *N-myc* amplification with stage III and IV neuroblastomas may indicate, therefore, that neuroblastomas comprise several classes of tumours, only one of which is characterized by *N-myc* amplification. We suggest this because primitive neuroectodermal tumours are characteristically difficult to distinguish from one another¹⁸; the heterogeneity among neuroblastomas now suggested by amplification of *N-myc* in only some tumours could therefore have gone undetected by more conventional criteria.

This study was supported by grants from the NIH (CA12705 and RR05355), the National Cancer Institute, the American Cancer Society and the G. W. Hooper Research Foundation. We thank Chris Lau for the gift of a cosmid library from a normal human individual, Jay Ellison for help in isolation of clone pNb-101, and Mike Scott for providing the LTR clone pMP-1. M.S. thanks Nissim Hay for stimulating discussions.

Note added in proof: In a separate set of experiments we have now shown that *N-myc*, when co-transfected into rat embryo cells together with a gene conferring resistance against neomycin, is capable of both inducing an increased number of neomycin-resistant cells and establishing, for more than 120 cell divisions so far, host cells with morphology similar to that of cells derived from type II foci. These cells have a higher serum requirement than those derived from type II foci (details will be published elsewhere).

The class I major histocompatibility antigen gene activated in a line of SV40-transformed mouse cells is *H-2D^d*, not *Qa/Tla*

Paul M. Brickell, David S. Latchman, David Murphy, Keith Willison* & Peter W. J. Rigby

We have previously described several complementary DNA clones isolated because they correspond to messenger RNAs present at higher levels in the simian virus 40 (SV40)-transformed BALB/c 3T3 cell line SV3T3 Cl38 than in the normal, parental BALB/c 3T3 line¹. One of these clones, pAG64, hybridizes to RNAs which, while present in BALB/c 3T3 cells, are 10-20-fold more abundant in SV3T3 Cl38 and are found at high levels in a wide variety of transformed cell lines^{1,2}. Nucleotide sequence analysis showed that pAG64 encodes a class I antigen of the major histocompatibility

complex². To ascertain the identity of pAG64, we compared its sequence with the available sequences of *d* haplotype class I antigen genes [*K* locus³, *L* locus⁴, *D* locus⁵ and the *Qa* gene defined by genomic clone 27.1 (ref. 6)] and found that it showed multiple clustered differences from each of these sequences². We therefore concluded that it was not derived from the *H-2K^d*, *H-2L^d* or *H-2D^d* genes and thus must correspond to one of the other class I antigen genes, namely those of the *Qa/Tla* complex², although it was clearly not the *Qa* gene defined by the genomic clone 27.1. We now report subsequent findings which indicate that pAG64 in fact corresponds to the *H-2D^d* gene and not to a *Qa/Tla* gene.

We synthesized an oligonucleotide (nucleotides 716-733 in the sequence of pAG64) which should distinguish pAG64 from the other sequenced class I antigen genes of the *d* haplotype and used it to screen the BALB/c cosmid library of Steinmetz *et al.*⁷. We found that the oligonucleotide hybridized to the cosmid c18.1, which carries the *H-2D^d* gene, and to the cosmid 65.1 which carries two genes, 3 and 4 of cluster 1, from the *Qa2,3* region. Hybridization to the *H-2D^d* gene was unexpected in view of the sequence of this gene published by Margulies *et al.*⁵. Sher *et al.* have now reported⁸ the sequence of the cosmid c49.2, which carries the coding sequence of the *H-2D^d* gene. It is essentially identical to that of pAG64. Our conclusion that pAG64 did not correspond to *H-2D^d* was based on the sequence of the genomic clone Ch4a-D^d (ref. 5). Margulies *et al.* now report that the published sequence of this clone is incorrect⁹. They have re-determined the sequence of part of this clone and find that of 821 nucleotides sequenced, 821 are identical to the sequence of Sher *et al.* and that in the region of overlap, 299 nucleotides out of 300 are the same as pAG64. We therefore conclude that pAG64 corresponds to the *H-2D^d* gene and not to a *Qa/Tla* gene.

The other reason that led us to assign pAG64 to *Qa/Tla* was our inability to detect homologous transcripts in various normal mouse tissues which express *H-2* but not *Qa* and *Tla* antigens. We now know that this was an artefact of our mRNA isolation procedure. All of the samples used in our previous publications were prepared by lysing the cells in a buffer containing Nonidet P-40, separating nuclei from cytoplasm and extracting RNA from the cytoplasmic fraction¹⁰. However, when we extract total RNA by the guanidine isothiocyanate procedure¹¹, we observe, as expected, appreciable levels of RNA homologous to pAG64 in various mouse tissues. We had always reprobed our blots with a cDNA clone for the mitochondrial transcript encoding cytochrome oxidase subunit 1 and had observed a clear band of the expected size and intensity. Therefore, it seems that the use of mitochondrial probes does not represent an adequate control. We stress that, irrespective of the method of RNA isolation, we observe much higher levels of class I mRNA homologous to pAG64 in SV40-transformed cells than in their normal parents. Similar results have since been reported by others for other virus-transformed and virus-infected cells^{12,13}.

We conclude that pAG64 is a cDNA clone corresponding to the *H-2D^d* gene and that high levels of this RNA are present in the SV40-transformed cell line SV3T3 Cl38. Whether the abundant class I antigen transcripts detected in other transformed cell lines are all derived from the *H-2D* gene is not known. Although our discussion of the possible roles of *Qa/Tla* antigens in normal and transformed cells² should be disregarded, the induction of class I antigen gene expression in transformed cells is clearly of interest and we are presently analysing the mechanisms involved¹⁴.

We regret the confusion that the mis-assignment of this clone has caused.

An enhancer-like sequence within the *Xenopus* U2 gene promoter facilitates the formation of stable transcription complexes

Iain W. Mattaj, Susanne Lienhard, Josef Jiricny* & Eddy M. De Robertis

Biocenter, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

*Friedrich Miescher Institut, PO Box 2543, CH-4002 Basel, Switzerland

Enhancers are eukaryotic promoter elements that increase transcriptional efficiency in a manner relatively independent of their position and orientation with respect to a nearby gene¹⁻³. There is growing evidence that enhancer action is mediated by *trans*-acting factors⁴⁻⁸, but the mode of action of these factors is not yet known. We report here on the *Xenopus* U2 gene promoter, which contains two sequence elements. The distal sequence element increases promoter activity 20-fold by facilitating the formation of stable transcription complexes. A synthetic 14-base-pair (bp) oligonucleotide corresponding to part of the distal sequence element, which shows homology to an immunoglobulin gene promoter element and to both the simian virus 40 (SV40) and the immunoglobulin heavy-chain gene enhancers, stimulates transcription in an orientation-independent manner.

The promoter of the *Xenopus* U2 snRNA gene¹⁰, in common with other vertebrate U snRNA genes¹¹⁻¹³, has no sequences homologous to the standard elements (TATA box, CCAAT box) found in the 5' control regions of most RNA polymerase II transcribed genes (reviewed in ref. 14). Pioneering studies on the human U1 gene promoter^{12,15} have shown that sequences essential for transcription of this gene in *Xenopus* oocytes lie between 203 and 230 bp upstream of the cap site. Recent work has shown that efficient transcription of a human U2 gene requires sequences located between 258 and 198 base pairs upstream of the cap site¹⁶, although 62 base pairs of 5' flanking sequence are sufficient to accurately direct transcription initiation in *Xenopus* oocytes⁹.

We have analysed the *Xenopus* U2 gene promoter by constructing a series of deletions removing parts of the 5' and 3' flanking sequences and assaying the transcription of the deletion mutants following microinjection into the nuclei of *Xenopus* oocytes. The extent of the deletions is shown in Fig. 1A. The gene indicated as *M* is a maxigene created by inserting 21 bp into the *Sau3A*I site between positions 28 and 32 of the U2 coding sequence¹⁰. The transcripts arising from mutants *a-h* are shown in Fig. 1B. Three conclusions can be drawn from the results shown in Fig. 1B. First, deletion of sequences between -82 and -55 (including the proximal element) eliminates U2 transcription (Fig. 1B, compare lanes *d*, *e*). Second, removal of sequences between -276 and -242 reduces the efficiency of transcription 10-20 fold (lanes *a*, *b*). No further reduction in transcriptional efficiency is seen on deletion of the sequences between -242 and -82 (lanes *b*, *c*, *d*). Third, deletion of sequences 3' to the U2 coding sequence up to 36 bp from the end of the coding sequence has no apparent effect on transcription (lanes *g*, *h*, *d*).

We next co-injected equal quantities of deletion mutant and

Fig. 1 Transcriptional activity of mutant U2 genes with progressive deletions of flanking sequences. **A**, Diagrammatic representation of the extent of the various deletions. U2-5 was recloned from pXIU2-5 (ref. 10) into M13mp8 (ref. 28) and in this paper is referred to as wild-type U2. The 188-bp coding sequence is indicated as well as the length of flanking 5' and 3' sequence remaining. DSE and PSE are the distal and proximal sequence elements, and are described in the text. **M** is a maxigene made by the insertion of 21 bp into the U2 coding sequence. All the deletions are cloned in the same orientation in M13mp8 (ref. 28). **B**, Transcription of the U2 mutants after microinjection into *Xenopus* oocytes. Lane C, control oocyte, injected only with [α^{32} P]GTP. Lanes U2-h, oocytes injected with either U2 or one of the mutant U2 genes in Fig. 1A. The lanes are lettered corresponding to the mutant injected. U2 and maxigene transcripts are indicated, as are the endogenous 8S¹⁰, 5.8S, and 5S rRNAs. **C**, Transcription of U2 mutants after coinjection with the U2 maxigene. Lane C, control oocyte. Lanes U2 and M, oocytes injected with only U2 or maxigene DNA. Lanes M+U2 to M+e, oocytes coinjected with an equal amount of maxigene DNA and either U2 or mutant a to e DNA.

Methods. The construction of mutants a-c and e-h is described elsewhere²⁹. Mutant d is a *Fnu*4HI restriction fragment of pXIU2-5¹⁰, repaired with T4 DNA polymerase and cloned into *Sma*I digested M13mp8 (ref. 28). The maxigene was constructed by sub-cloning the two *Sau*3AI fragments of pXIU2-5 separately into the *Bam*HI site of M13mp8, excising them with either *Eco*RI-*Hinc*II or *Hind*III-*Sma*I double digests, and ligating them back into *Eco*RI-*Hind*III digested M13mp8 in their original configuration with the insertion of an *Xho*I linker between the *Sma*I and *Hinc*II ends. Microinjection and transcript analysis were performed exactly as in ref. 10. Relative transcription levels were estimated by scintillation counting of excised bands.

maxigene DNA to have an internal standard when comparing the transcriptional efficiency of various mutants. The results of this experiment are shown in Fig. 1C. The wild-type U2 and the maxigene are roughly equally transcribed on coinjection (Fig. 1C, lane M+U2). Mutant a, deleted from -358 to -276, which shows wild-type activity when injected alone (Fig. 1B, lane a), can still compete, although with a reduced efficiency compared to wild-type U2, when coinjected with maxigene (lane M+a). Mutants b, c and d, all of which are transcribed although at a reduced level when injected singly (Fig. 1B, lanes b-d) do not produce transcripts detectable above the level of endogenous U2 when co-injected with maxigene (Fig. 1C, compare lane M with lanes M+b, M+c, M+d).

The *Xenopus* U2 genes are tandemly repeated¹⁰. A construct which includes all the sequences up to -652, that is, to the prior coding sequence, behaves identically to the U2 clone with 358 base pairs of 5' flanking sequence in both single injection and coinjection experiments (data not shown), indicating that all the 5' flanking promoter elements necessary for full transcriptional activity in oocytes lie between -358 and -1. These results suggest that there must be a factor in oocyte nuclei whose concentration is rate-limiting for U2 gene transcription in these experiments. Sequences upstream of -242 are necessary for efficient association with this factor, such that when a gene with these sequences and a mutant in which they have been deleted are placed in direct competition, only the gene with the distal sequence element will be transcribed. In the absence of competition the factor can weakly associate with mutant genes lacking the distal sequence element, resulting in a lower level of transcription.

Mutant genes having only the proximal sequence element are thus weakly transcribed. We have made promoter constructs in which the proximal sequence has been deleted but in which the distal sequence element remains. These do not give rise to transcripts (data not shown) showing that the proximal sequence element is essential for transcription.

A characteristic of transcription complexes formed on genes transcribed by RNA polymerases III^{17,18} and I¹⁹ is that once formed, they are stable. Transcription factors remain closely associated with their DNA binding sites during many rounds of transcription. The competition experiments described above suggest that the distal sequence element is necessary for the association of a transcription factor. To test whether this association is also stable (through many rounds of transcription), competition experiments were performed in which two U2 constructs were microinjected consecutively rather than simultaneously. The first four lanes of Fig. 2 show that prior injection of vector DNA has no effect on the transcription of subsequently injected U2, maxigene, or mutant d DNA. This means that factors required for transcription do not associate stably with vector DNA. When U2 and maxigene DNA are coinjected, both are equally transcribed (Fig. 1C, lane M+U2). When they are consecutively injected, however, only the DNA injected first is efficiently transcribed (Fig. 2, lanes M+U2 and U2+M). This result suggests that transcription factors, at least one of which is limiting in concentration in these experiments, associate with the first injected DNA during the 3-h incubation, and that these complexes do not dissociate significantly during the following 20 h, that is, during many rounds of transcription. We estimate from Northern hybridizations that at least 10 transcripts per

Fig. 2 Sequential injection of wild-type and mutant U2 genes. Oocytes were microinjected into the nucleus with one DNA, incubated for 3 h, microinjected with a second DNA, incubated for a further 3 h, then microinjected into the cytoplasm with [α^{32}]GTP. Twenty hours later RNA was extracted and analysed from single oocytes. The DNAs injected first and second are indicated. V, vector (M13mp8) DNA; U2, U2 DNA; M, maxigene DNA; d, mutant d DNA. Although only a single oocyte for each combination is shown, between 10 and 30 single oocytes were analysed in each case. The oocytes shown are representative of the most frequent (at least 70%) result obtained with each combination of injections. Some oocytes do not conform to the most frequent result, due to inaccurate microinjection such that some or all of one of the DNAs injected was not deposited in the nucleus, and thus was not transcribed. The main result, that genes lacking the distal sequence element cannot form stable transcription complexes, was obtained in three different experiments involving analysis of 30 individual oocytes.

injected gene accumulate during a 20-h incubation (data not shown). As the proportion of the injected genes assembled into active transcription complexes is unknown, the actual figure of transcripts per active gene could be significantly higher.

To determine the sequence requirements for this stable binding, we injected consecutively maxigene and mutant DNAs. The results for mutant d (Fig. 2) and mutant b (not shown), both of which lack the distal sequence element, were identical. Independent of whether the mutant DNA was injected before or after the maxigene, only the maxigene was efficiently transcribed (Fig. 2, lanes M + d and d + M). This shows that sequences >242 bases upstream of the cap site, likely to be identical to the distal sequence element identified in the previous section, are required for the formation of stable transcription complexes.

A sequence comparison of the region between positions -242 and -358 with other sequenced U snRNA genes revealed that homologous sequences are found in a *Xenopus* U1 gene³⁰ and a human U1 gene^{12,15} (Table 1). The human homology is part of the stretch between -203 and -230 previously shown to be necessary for transcription of this gene in *Xenopus* oocytes¹⁵. The *Xenopus* U1.3 gene can compete efficiently with the U2 gene on coinjection. Removal of sequences upstream of -216 from XIU1.3, including the homologous region shown in Table 1, results in the loss of this competitive ability (data not shown). A related sequence occurs in the promoter of immunoglobulin heavy-chain genes^{20,21} (Table 1), and in the promoters of immunoglobulin light-chain genes in the opposite orientation^{20,21}. A strongly homologous sequence is also present in the SV40 enhancer^{21,22} and, in the opposite orientation, in the

Comparison of part of the U2 gene promoter with sequences found in a human U1 gene¹² and a *Xenopus laevis* U1 gene³⁰. They are compared with sequences found in the 5' flanking region of immunoglobulin genes of mice and men^{20,21} and of the SV40^{21,22} and immunoglobulin enhancers. The numbers on the right indicate the distance from the transcription initiation site. The sequence of a synthetic oligonucleotide, designed to test the functional importance of the conserved sequence is also shown. The *Xenopus* U2 sequence is extended to the left to indicate the extent of sequence conservation between *Xenopus*¹⁰, rat²⁷ and human^{9,16} U2 gene promoter sequences. This extended homology is not found in the U1 genes so far sequenced.

immunoglobulin heavy-chain gene enhancer⁸.

To test directly whether this homology is functionally significant, two 19-b complementary oligonucleotides, corresponding to the 14 b between -269 and -256 of the U2 promoter flanked by *Bam*HI linker ends (Table 1), were synthesized. This oligonucleotide duplex was then inserted into two mutants, b and d, both of which lack the distal sequence element. The site of insertion in mutant b, -242 (Fig. 3A), was such that the oligonucleotide was restored close to its original position. The sites of insertion into mutant d were at -82 in the 5' flanking region and +36 in the 3' flanking region (Fig. 3A). The orientation of insertion was determined by DNA sequencing and the clones designated 242+, 242-, 82+, 82-, 3'/36+ and 3'/36-, a plus sign indicating that the insert had the same orientation as in wild-type U2, a minus sign that the insert was inverted (represented by arrows in Fig. 3A). We then coinjected these DNAs with an equal concentration of either maxigene M (Fig. 1A), which has a complete promoter, or a new maxigene construct called dM which was made by joining the promoter of mutant d (Fig. 1A) to the coding region of the maxigene. Mutant dM therefore lacks the distal sequence element. Figure 3B shows the results of competition experiments with this gene. On coinjection, mutants d and dM are equally transcribed (Fig. 3B, lane 2), as are mutants b and dM (not shown). This is expected as these clones all lack the distal sequence element but retain the proximal sequence element. On coinjection of U2 and dM, only U2 transcripts are seen (Fig. 3B, lane 3), because U2 contains the distal sequence element. Mutants 242+ and 242- both show intermediate behaviour, being expressed to a much greater extent than dM regardless of the orientation of insertion of the synthetic oligonucleotide, but a small amount of dM transcription is still detectable (Fig. 3B, lanes 4, 5). These results indicate that insertion of the 14-b synthetic oligonucleotide, corresponding to part of the U2 promoter (Fig. 3A), into a site close to its natural position, results in partial complementation of distal sequence element function. This complementation is independent of the orientation of the insertion of the oligonucleotide despite the fact that it shows no rotational symmetry. To test whether the oligonucleotide would function independently of the position of insertion we next coinjected dM with clones 82+, 82-, 3'/36+ and 3'/36-. The result in Fig. 3B, lane 6 shows that clone 82+ competes efficiently with dM (more efficiently than either 242+ or 242-). The transcript produced

Fig. 3 The *Xenopus* U2 gene. The 188-bp coding region is indicated by the interrupted black rectangle. The positions of conserved sequences representing at least parts of the distal and proximal promoter sequence elements are shown. The TCTCCNNATG sequence was described²⁹ as a sequence element conserved in all *Xenopus* U snRNA genes so far analysed. The arrows above -242, -82 and +36 represent the position and orientation of insertion into the flanking sequences of a synthetic oligonucleotide described in the text and Table 1. **B**, Insertion of a 19-bp synthetic oligonucleotide restores distal sequence element function in an orientation independent manner. Mutant *dM*, constructed by combining the promoter of mutant *d* with the coding sequence of the maxigene through the *Nco*I site at -55, was coinjected with either U2, mutant *d* or a series of clones constructed by inserting a 19 bp synthetic oligonucleotide duplex into mutants *b* and *d* and termed 242+, 242-, 82+, 82-, 3'/36+ and 3'/36- depending on the position and orientation of insertion of the oligonucleotide (Fig. 3A). A plus sign indicates that the oligonucleotide is in the same orientation as in U2-5, a minus sign that it is in the inverse orientation. The two DNAs were coinjected at equal concentration. Lane 1, control oocyte; lane 2, *dM*+*d*, lane 3, *dM*+U2; lane 4, *dM*+242+; lane 5, *dM*+242-; lane 6, *dM*+82+; lane 7, *dM*+82-; lane 8, *dM*+3'/36+; lane 9, *dM*+3'/36-. The U2 and *dM* transcript sizes are indicated. Equal transcription of *dM* and the competitor clone indicates that neither clone can stably bind to a limiting transcription factor. Excess of transcription over *dM* indicates that the competitor clone can bind the factor required for the formation of stable transcription complexes.

from this mutant is slightly longer than U2, which probably results from the close proximity of the distal and proximal sequence elements in this construct affecting the accuracy of transcription initiation. Mutant 82- is transcribed equally to *dM* (Fig. 3B, lane 7) indicating that at this position insertion of the oligonucleotide in inverted orientation has no effect on promoter efficiency. Similarly, insertion of the oligonucleotide in either orientation into the 3' flanking region in clones 3'/36+ and 3'/36- has no effect on promoter efficiency (Fig. 3B, lanes 8, 9). These results were confirmed by testing the oligonucleotide-containing genes against maxigene *M* (Fig. 1A). 242+, 242- and 82+ could all compete to a limited but significant extent with maxigene *M*, whereas 82-, 3'/36+ and 3'/36- could not (data not shown).

Insertion of the synthetic oligonucleotide in either orientation near to its natural position (constructs 242+ and 242-) or 170 base pairs nearer to the cap site in the normal orientation (82+) therefore results in partial restoration of the competitive ability of mutants *b* and *d*. The reason for the restoration being incomplete is probably because the 14 bp of promoter sequence inserted do not represent the entire distal sequence element, but only part of it. In this context the behaviour of mutant *a* in competition with the maxigene is of interest. This mutant, deleted from -358 to -276, to within 7 bp of the homology shown in Fig. 3A, competes less efficiently than U2 with the maxigene (Fig. 1C compare lane *M*+*a* with lane *M*+U2). An explanation for this would be that part of the distal sequence element has been removed in this mutant.

The independence of orientation and, to some extent, of position of insertion of the oligonucleotide suggests that the distal sequence element is enhancer-like. It has been reported previously that viral enhancers are not completely position independent^{2,3}. As the oligonucleotide seems to represent only part of the promoter element this might mean that it would be more subject to effects of the sequences flanking its insertion site. The fact that 82+ competes more efficiently than either 242+ or 242- with both maxigene and mutant *dM* (compare lane 6 with lanes 4, 5 in Fig. 3B) suggests that such position effects can be positive as well as negative.

The *Xenopus* U2 gene promoter contains two elements necessary for maximal transcriptional activity in *Xenopus* oocytes. The distal of the two elements is required for full promoter efficiency, while the proximal sequence element is

essential for transcription. The bipartite nature of the U2 promoter is consistent with results obtained by other laboratories working with U snRNA gene promoters^{9,15,23,24}.

The formation of stable transcription complexes has been shown to be an important step in transcription by RNA polymerases I and III¹⁷⁻¹⁹. In the case of RNA polymerase III transcription the DNA sequences necessary for stable complex formation are internal to the genes¹⁷. The DNA element necessary for stable RNA polymerase I complexes is an enhancer, that is, is orientation and position independent²⁵. The results presented here show that the formation of stable transcription complexes is also a step in RNA polymerase II transcription *in vivo*. In addition the DNA sequence element required for their formation acts independently of orientation, that is, it has some of the properties of an enhancer. This suggests that the function of enhancers in general is to promote the formation of stable transcription complexes, a hypothesis that could be tested experimentally with better characterized enhancers in other gene systems, such as SV40 or polyoma. The U2 distal sequence element function is partly restored by insertion of a synthetic oligonucleotide containing only 14 base pairs of U2 promoter sequence. This sequence does not display rotational symmetry, and does not appear to be repeated within the U2 tandem repeat unit. Surprisingly, the first 8 b of these 14 are identical to a sequence element found roughly 60 base pairs 5' of the cap site of mammalian immunoglobulin heavy-chain genes^{20,21} (Table 1). This element is found in the same position, but in the opposite orientation, in the promoter of immunoglobulin light-chain genes^{20,21}. This sequence also has a counterpart in the SV40 enhancer^{21,22} (Fig. 3A), and is also present, in the opposite orientation, in the immunoglobulin heavy-chain enhancer⁸ (Fig. 3A). In fact the G residue located in this sequence is protected against dimethyl sulphide modification in cells of the B lineage, but not in other cell lines⁸. This suggests that this sequence, within the immunoglobulin heavy-chain enhancer, interacts with a factor in B cells, and this is likely to be important in bringing about the cell-type specific expression of the immunoglobulin genes. These data support the notion that this element is a general, orientation independent promoter element. The eight absolutely conserved bases may represent the core of the element, whose activity could be modified by non-conserved sequences in the immediate vicinity. It may be that the distinction between enhancers and other upstream promoter elements will

become more tenuous as we understand more about how they function. Note that the first orientation-independent promoter element was found when a restriction fragment upstream of the sea-urchin H2A histone gene was inverted²⁸.

We thank John Shepherd for carrying out the computer searches and for comments on the manuscript. We also thank Tom Bickle, Roman Klemen, Peter Nielsen, Rolf Zeller, Denise Smith, Christopher Wright, Andreas Fritz and Thomas Bürglin for helpful comments and Christel Riedel for typing the manuscript. This work was supported by a grant from the Swiss National Science Foundation.

Note added in proof: Recent experiments carried out in collaboration with Angelo Tognoni and Walter Schaffner have shown that in CV1 (Monkey) cells the *Xenopus* U2 distal sequence element can functionally replace the SV40 enhancer to allow replication and T-antigen expression in SV40 mutants lacking the SV40 enhancer.

Amplification of *inter-Alu* extrachromosomal DNA during cellular ageing: retraction and explanation

R. J. Shmookler Reis, C. K. Lumpkin Jr*, J. R. McGill*, K. T. Riabowol & S. Goldstein

University of Arkansas for Medical Sciences, Departments of Medicine & Biochemistry, Division of Gerontology Research, and Veterans Administration Medical Center, Little Rock, Arkansas 72205, USA

We reported previously^{1,2} the age-dependent appearance of extrachromosomal circular DNA bands hybridizing to a human DNA fragment ('*inter-Alu*'), isolated from a genomic cluster of *AluI* repeats. Such bands appeared or increased at late passage in four out of six human fibroblast strains (six out of nine cell expansions); moreover, all DNAs (9/9) obtained from peripheral lymphocytes of aged donors, but none (0/8) from young donors, revealed a non-genomic *inter-Alu* band at ≈ 4.8 kilobases (kb)^{1,2}. Subsequent data extended these numbers to 16/24 aged donors compared with 0/18 young donors³. These results were interpreted as evidence of age-dependent DNA rearrangement in normal human cells^{1,2}. We now report that the 'extra' bands were of microbial origin, although clearly occurring in an age-dependent manner.

The hybridizations reported^{1,2,4} primarily used the entire *inter-Alu*-containing plasmid, pAH15A, as ³²P-DNA probe. Gel-purified insert DNA also hybridized to the extrachromosomal species, which was then believed to be an adequate control for plasmid contamination. Such hybridization, however, could still be due to residual traces of vector DNA, "invariably present in [insert] probes ... even after two cycles of electrophoretic purification" (ref. 5). Control hybridizations against many of the same

DNA preparations, with a pCR1 fragment or pBR322 plasmid containing other inserts, revealed no extra bands. However, when we obtained the parental vector for *inter-Alu*, pACYC184, we observed hybridization of this probe to the age-dependent bands in both fibroblast and lymphocyte DNA samples, indicating that such bands must be due to low levels of microbial plasmid DNA ($\approx 10^{-6}$) in our human DNA samples. We discussed the dangers of microbial contamination¹, but were misled by unwarranted confidence in the controls, the pervasive extent and polymorphic nature of the contamination, and its remarkable age dependence.

In attempting to account for our data, we have considered the possibility of deliberate contamination and regard it as extremely unlikely. Inadvertent operator contamination, however, is difficult to reconcile with the marked age bias observed, in particular for the multiple fibroblast DNA bands seen in many independent samples, prepared by six persons over a 2-yr period. Biological contamination is more plausible in the light of recent reports of microbial plasmid DNA in biopsy and necropsy tissue samples and in body fluids⁵⁻⁷. Our preliminary evidence indicates that plasmid-homologous DNA can be detected in filter-sterilized serum and trypsin, two common reagents for cell culture. Thus, the correlation between culture age and plasmid bands may reflect cumulative exposure of fibroblasts to plasmid DNA.

We apologize for any inconvenience to other investigators resulting from this error. Our experience, along with other reports^{5,6,8}, underscores the danger of systematic plasmid contamination of DNA samples, and the necessity for control hybridizations using the appropriate vector alone as probe.

In vitro reactivation of anaphase spindle elongation using isolated diatom spindles

W. Zacheus Cande & Kent L. McDonald

Department of Botany, University of California, Berkeley, California 94720, USA

A key step for analysing the mechanochemistry of mitosis would be the isolation of a functional spindle capable of anaphase chromosome movement *in vitro*. Although Mazia and Dan first isolated spindles in 1952¹, with one or two possible exceptions²⁻⁴, isolated spindles are non-functional (reviewed in ref. 5). An alternative approach has used permeabilized cells to study anaphase chromosome movement⁶⁻¹⁰, but these preparations are biochemically and morphologically complex, and hence difficult to analyse. We describe here a simple procedure for isolating diatom spindles which are capable of anaphase spindle elongation *in vitro*. With addition of ATP, the two half-spindles slide completely apart, with concomitant decrease in the zone of overlap. Electron microscopy reveals decreased numbers of microtubules throughout the spindle after ATP addition and confirms the complete absence of structures beyond the spindle poles. These results are inconsistent with theoretical models of mitosis which suggest that spindle poles are pushed apart by microtubule growth¹¹, are pulled apart by external forces applied to the poles¹²⁻¹⁵, or are

released from tension generated during spindle formation¹⁶. The results are consistent with models that postulate mechanical interactions in the zone of microtubule overlap as a factor in spindle elongation^{17,18}.

Diatom spindles are important model systems for studying the morphological changes associated with anaphase chromosome movement because the central spindle microtubules are arranged in paracrystalline arrays and the microtubules associated with chromosome-to-pole movement (anaphase A) are spatially separated from the microtubules associated with spindle elongation (anaphase B)^{19,20}. Morphometric analysis has shown that the diatom central spindle is constructed of two half-spindles which exhibit specific near-neighbor interactions in the zone of overlap²¹. This microtubule overlap zone, which is visible even by light microscopy, decreases as the central spindle elongates during anaphase B²².

The centric diatom *Stephanopyxis turris* was selected as starting material because it can be grown in large quantities in a simple medium and its cell cycle is easily synchronized (L. Wordeman, K.L.Mc.D and W.Z.C., in preparation). Following homogenization, spindles are isolated by a two-step procedure consisting of filtration to remove cell walls and low-speed centrifugation of spindles onto coverslips (Fig. 1). The central spindle is readily detected as a phase-dense bundle of fibres embedded in a tangled mass of chromatin (Fig. 1a). In polarization optics, the central spindle is a highly birefringent structure with a prominent zone of microtubule overlap, showing increased birefringence, which is 15-25% of the total spindle length (Fig. 1b, Table 1).

Addition of 1mM ATP by perfusion leads to an increase in

Fig. 1 Changes in spindle structure after reactivation as monitored by light microscopy. *a*, An isolated spindle viewed with phase optics. Note the prominent phase-dense overlap zone and the tangled mass of chromatin. *b*, An isolated spindle viewed with polarization optics with negative compensation, just before ATP addition (0 min) and after addition of 1 mM ATP (at 5 min, 10 min, 15 min). Note the decrease in the birefringence in the zone of microtubule overlap during spindle elongation. There is further loss of birefringence from the midzone even after elongation is complete. The spindle elongated at a rate of $0.3 \mu\text{m min}^{-1}$. Scale bar, $2 \mu\text{m}$. *c*, Change in extent of birefringence of the zone of microtubule overlap (●) during spindle elongation (spindle length; ○) on addition of 1 mM ATP at time 0. Midzone birefringence continues to decrease after elongation is complete. The rate of elongation in this example, which differs from *b*, is $\sim 0.1 \mu\text{m min}^{-1}$. Normal anaphase spindle elongation occurs at a rate of $1-2 \mu\text{m min}^{-1}$ and the increase in spindle length is much greater than the size of the overlap zone. Some of this length increase must be due to microtubule growth (data not shown).

Methods. Cells were grown in f/2 medium³⁰ in a suspension culture on 6-h-day, 18-h-night schedule at 19°C . Three hours before collection 2×10^{-8} M nocodazole was added and 20 min before collection, cells were placed on 60- μm mesh Nitex filters and washed extensively to remove the drug. Cells were collected by filtration at the height of the division peak which occurred $1\frac{1}{2}$ -2 h after night began. Cells were resuspended in homogenization medium at room temperature (50 mM PIPES, pH 7.0, 40 mM sodium glycerophosphate, 10 mM MgSO_4 , 10 mM EGTA, 0.2% Brij 58, 30% glycerol, 1 mM dithiothreitol (DTT) and inhibitors of proteolysis³¹, then homogenized on ice with two strokes of a Kontes Dounce homogenizer, B pestle. The homogenate was filtered once through 60- μm mesh and once through 25- μm mesh Nitex filters, then centrifuged for 20 min, 0°C at 2,000 g onto coverslips. Coverslips were mounted on slides, using strips of Parafilm as spacers, waxed down with Valap⁷, and then perfusion was performed as described previously for lysed cells⁸. Reactivation medium consisted of 50 mM PIPES pH 7.0, 5 mM MgSO_4 , 10 mM EGTA, 1 mM ATP, 1 mM DTT, with or without 7.5% glycerol. The progress of reactivation was monitored with Zeiss polarization optics, 40 $\times$ Nikon rectified lens, Bracke-Kohler A/30 compensator and a DAGE-MTI low light level television camera connected to a Panasonic time-lapse video recorder. Two KG1 heat filters, a 1.5-inch column of saturated copper sulphate solution, and a narrow-pass green interference filter were placed between the 100-W mercury light source and the condenser to minimize damage to the spindle. The isolation medium was designed to stabilize the microtubule components of the spindles, but it was necessary to include protease and phosphatase inhibitors to obtain reliable reactivation of spindle function. Although yield is low, the coverslips are covered with hundreds of spindles at a similar stage of mitosis (metaphase to early anaphase); the only contaminants present are interphase nuclei, chloroplasts and glass cell wall fragments.

Fig. 2 Electron microscopy of isolated spindles with (*b, d*) and without (*a, c*) added ATP. *a*, Spindle pole structure showing the mitotic centre (MC) or centrosome at the end of the obliquely sectioned spindle (S). No cytoplasmic structures extend beyond the pole. $\times 28,500$. *b*, Longitudinal section through the middle of an isolated spindle after 10 min in 1 mM ATP. The few remaining MTs in this region are abnormally curved (arrows). $\times 11,000$. *c*, Cross-section through the overlap region in an isolated anaphase spindle (minus ATP). There are 623 hexagonally packed microtubule profiles in this section. $\times 41,000$. *d*, Cross-section through the overlap region in an ATP-treated spindle of comparable mitotic stage with the one in Fig. 2*c*. There are 108 microtubule profiles in this section. This spindle is very close to where the coverslip was (arrow) before it was dissolved with HF before sectioning. $\times 41,000$.

Methods. Isolated spindles attached to coverslips were fixed with 0.5% glutaraldehyde in f/2 medium³⁰ for 30 min at 23 °C (unless otherwise stated, all remaining steps were at 23 °C). Spindles were rinsed for 5 min in f/2, then 5 min in PBS (physiologically buffered saline: 137 mM NaCl, 2.68 mM KCl, 8 mM $\text{Na}_2\text{HPO}_4/\text{H}_2\text{O}$, 1.47 mM KH_2PO_4) at pH 7.3, fixed in 0.2% $\text{OsO}_4 + 0.3\%$ $\text{K}_3\text{Fe}(\text{CN})_6$ in PBS for 15 min at 4 °C, rinsed twice in PBS for 5 min each, rinsed in distilled H_2O for 5 min, incubated in 2% aqueous uranyl acetate for 90 min, dehydrated in acetone by 10% steps for 10 min each, and embedded in Epon-Araldite.

spindle length and a concurrent decrease in the magnitude and extent of birefringence in the zone of microtubule overlap (Fig. 1*b, c*). Within 5 min after ATP addition, spindles begin to elongate at a rate of 0.1–0.4 μm per min for several minutes. After spindle elongation is complete, the birefringence in the spindle midzone continues to decrease. In the example shown in Fig. 1*b*, the two half-spindles have become disengaged and the extent of birefringence of each half-spindle has shortened by $\sim 1 \mu\text{m}$.

For all of the spindles studied on-line by video microscopy (Table 1), we find that the increase in spindle length is about the same as the length of the microtubule overlap zone and that spindle midzone birefringence always continues to decrease after elongation is complete. The sample size in Table 1 is necessarily small because the isolated spindles are easily damaged by the manipulations required for on-line observations. It is easier to study the physiology of spindle elongation using populations of spindles (see Table 2). After incubation for 10 min in 1 mM ATP, >85% of the spindles on a coverslip show distinct midzone birefringence changes. Those spindles which display reduced birefringence are significantly longer than control (minus ATP) spindles or spindles which do not have reduced midzone birefringence.

Longitudinal sections and serial cross-sections of *in vitro* spindles show that the mitotic centre is retained during isolation (Fig. 2*a*) and that no other structures extend beyond the end of the isolated central spindle. The overlap zone is the region most drastically altered by ATP. Normally the most well-ordered part

of the spindle^{19–21}, the overlap is in complete disarray after 10 min in 1 mM ATP (Fig. 2*b*). Isolated spindles (minus ATP) were similar to *in vivo* spindles in the number of microtubules per half-spindle (~ 300) and extent of microtubule overlap at early anaphase ($\sim 20\%$). After 10 min in 1 mM ATP, the number of microtubules present drops to about 110–120 per half-spindle, and relatively few microtubules are found in the overlap region (Fig. 2*d*) compared with control spindles (Fig. 2*c*).

The newly formed gap between the half-spindles is not due just to microtubule depolymerization. The microtubules in the isolated central spindles are very stable and the birefringence pattern shown in Fig. 1*b*, 0 min, will persist for several hours in the absence of ATP. Addition of nonspecific agents which promote microtubule depolymerization, such as high salt, do not lead to gap formation, but rather to a decrease in overall birefringence and some spindle shrinkage. This shows that ATP addition leads not only to spindle elongation but also to a defined pattern of microtubule disassembly, starting from the midzone and working poleward. We suggest that the mechanochemical events leading to spindle elongation and the ATP-induced lability of microtubules *in vitro* are closely related. One possibility is that there is a discrete cap on the end of every microtubule in the overlap zone (the plus end^{23,24}) that regulates microtubule assembly–disassembly in an ATP-dependent manner. Alternatively, or in addition, lateral interactions between overlapping microtubules may stabilize them²⁰, and as the two half-spindles separate, giving less overlap, the microtubules begin to depolymerize. Either suggestion would be consistent

Table 1 *In vitro* spindle elongation monitored by video microscopy

Original spindle length (μm)	Final spindle length (μm)	Length change (μm)	Length of initial zone of microtubule overlap (μm)
9.3	11.0	1.7	1.8*
10.1	12.0	1.9	2.2*
6.3	7.5	1.2	1.1*
8.8	10.5	1.7	2.0†
8.3	10.0	1.7	2.0†
9.6	11.7	2.1	2.1†

* There was a distinct gap between half-spindles at the end of experiment.

† Spindle midzone was reduced in birefringence to same level as the rest of the half-spindle and the midzone was thinner or collapsed.

Table 2 Average spindle lengths of experimentally treated populations of spindles

Treatment	n	Average spindle length (μm)	Size of zone of microtubule overlap (μm)	Change in average spindle length (μm)
No ATP control	25	8.4 $\pm$ 0.9	1.9 $\pm$ 0.2	
Plus 1 mM ATP:				
Reduced overlap zone birefringence	26	10.7 $\pm$ 0.8*	†	2.3‡
No change in overlap zone birefringence	5	8.2 $\pm$ 0.6	1.7 $\pm$ 0.2	-0.2

Coverslips prepared as described in Fig. 1 legend were incubated for 10 min at room temperature in reactivation medium with or without ATP, then 0.5% glutaraldehyde was added. The lengths of individual spindles were measured off the TV monitor. All spindles on a transect of the preparation were used for these measurements, except it was necessary to disregard five or six spindles whose poles were not in good focus or were obscured by debris.

* The difference between the means (compared with no ATP) was statistically significantly different at $P < 0.001$ using Student's *t*-test.

† The average size of the gap between the two half-spindles was $0.7 \pm 0.3 \mu\text{m}$.

‡ As compared with average spindle length of control (minus ATP) spindles.

with the directed pattern of microtubule disassembly observed during telophase in the diatom *Pinnularia*²⁵ or after ultraviolet microbeaming of diatom spindles²⁶.

Anaphase chromosome movement is a complex process involving several distinct mechanochemical events (reviewed in refs 27, 28). Our observation of a loss of birefringence in the zone of microtubule overlap during reactivation of spindle elongation suggests that microtubule sliding is the key mechanochemical event that occurs during anaphase B. Ultraviolet microbeaming experiments on living dividing diatoms demonstrate that anaphase B *in vivo* also depends on the generation of sliding forces in the zone of microtubule overlap²⁹. Several investigators have suggested that dynein-like interactions between interdigitating sets of microtubules in the overlap zone may be responsible for spindle elongation^{17,18,20}. Although we cannot identify the motor, the requirement for ATP and inhibition of elongation by $10 \mu\text{M}$ vanadate (data not shown) suggests that a dynein-like ATPase may be involved. The observation that similar conditions affect spindle elongation in lysed mammalian cells¹⁰ suggests that an analogous mechanism may be important for anaphase B in a wide variety of cells.

The forces responsible for spindle elongation *in vitro* could not have been generated by microtubule polymerization¹¹, as no tubulin is present during reactivation. However, *in vivo* in this diatom and many other cells, microtubule growth is an integral part of anaphase B and leads to an increase in spindle length much greater than can be generated by microtubule rearrangements alone. The autonomy of the central spindle and

the lack of attachment of the spindle poles to any other cytoplasmic structures beyond the poles eliminates the possibility that the half-spindles are pulled apart by astral microtubule interactions with cytoplasmic components¹²⁻¹⁵. Although it has been suggested that spindle poles are self-propelled¹³, these phenomena may have more to do with nuclear migration and repositioning at the end of cell division than with anaphase B. Finally, it has been suggested that tension generated during spindle formation and released during chromosome-to-pole movement may be responsible for spindle elongation¹⁶. As little or no chromosome-to-pole movement occurs during spindle reactivation, this mechanism is also inconsistent with our observations.

We thank Dr Kevin Pfister and Linda Wordeman for helpful discussions, Ellen Dean, Dan Coltrin and Troya Bogard for technical assistance, and Dr David Bentley for access to his video camera. This work was supported by NIH grant GM23238 and NSF grant PCM-8408594.

β -Hairpin families in globular proteins

B. L. Sibanda & J. M. Thornton

Laboratory of Molecular Biology, Crystallography Department, Birkbeck College, Malet Street, London WC1E 7HX, UK

β -Hairpins, one of the simplest supersecondary structures, are widespread in globular proteins, and have often been suggested as possible sites for nucleation¹. Here we consider the conformation and sequences of the loop regions of β -hairpins by analysing proteins of known structure. We find that the 'tight' β -hairpins, classified by the length and conformations of their loop regions, form distinct families and that the loop regions of the family members have sequences which are characteristic of that family. The two-residue hairpin loops include almost entirely I' or II' β -turns, in contrast to the general preference for type I and type II turns^{2,3}. These findings are being used to help define templates or consensus sequences to be incorporated into our existing supersecondary structure prediction algorithm^{4,5}. This information can also be used in model-building homologous proteins.

Fig. 1 *a*, Distribution of the number of residues in the loop region for 107 β -hairpins. *b*, Schematic diagram of a β -hairpin. Data derived from the 62 proteins included in the Kabsch and Sander dictionary of secondary structure⁶. Loop residues are defined as those not participating in the antiparallel β -ladder⁶, which forms the hairpin. Residue 1 participates in the ladder if both its NH and CO groups form the standard antiparallel H-bonds, or if adjacent residues CO_{*i*-1} and NH_{*i*+1} form these bonds. If the first and last residue of the loop are linked by one hydrogen bond (NH_{*i*+1} to CO_{*i*-1}), this is denoted by an asterisk in Table 1. This definition is unequivocal and in practice is simple to apply to the Kabsch and Sander output. The ladder must include at least two residues in each strand, and only loops which do not include a helix or another strand are counted. For homologous loops (that is, >50% amino-acid identity), only one family member was included.

Fig. 2 Conformation of loop regions shown by plotting ϕ, ψ values for the loop residues. *a*, Classical β -turn conformation types I and II and their mirror images I' and II' taken from Chou and Fasman². These are defined by the ϕ, ψ values of the two central residues of the turn (usually referred to as residues 2 and 3) which in the context of, say, a two-residue hairpin, will be described as residues L1 and L2. The $\phi_{L1}, \psi_{L1}, \phi_{L2}, \psi_{L2}$ values plotted are type I = $-60^\circ, -30^\circ, -90^\circ, 0^\circ$; type I' = $+60^\circ, +30^\circ, +90^\circ, 0^\circ$; type II = $-60^\circ, 120^\circ, 90^\circ, 0^\circ$; type II' = $60^\circ, -120^\circ, -90^\circ, 0^\circ$. Since type III turns do not form a group distinct from the type I turns¹⁶, they have been omitted. Arrowheads denote the L2 ϕ, ψ value. *b*, ϕ, ψ Plot for the 29 two-residue hairpin loops given in Table 1. For each loop the ϕ, ψ values of residue L1 are connected by a line to the ϕ, ψ values of residue L2, with the arrowhead denoting the L2 position. Types I' and II' turns predominate, with only four type I turns, denoted by stars, and no type II turns, observed. *c*, ϕ, ψ Plot for the six four-residue hairpin loops with type I turns given in Table 1a. For each loop the ϕ, ψ values of residues L1, L2, L3 and L4 are plotted and joined together sequentially. Five of these hairpins also have residue L4 in the $+/+$ quadrant of the ϕ, ψ plot. The ϕ, ψ angles calculated by averaging over the four similar loops for residues L1 to L4 are $-62^\circ, -38^\circ, -58^\circ, -35^\circ, -101^\circ, -19^\circ, 75^\circ, 42^\circ$. *d*, ϕ, ψ Plot for the eight five-residue hairpin loops which form a family (see Table 1a). For each loop the ϕ, ψ values of residues L1, L2, L3, L4 and L5 are plotted and joined together sequentially. Note the type I turn for residues L2 and L3 and the positive ϕ values for residue L4. The standard ϕ, ψ angles for residues L1 to L5, calculated by averaging over the eight hairpins in the family, are $-90^\circ, 161^\circ, -56^\circ, -24^\circ, -92^\circ, 2^\circ, 95^\circ, 2^\circ, -85^\circ, 136^\circ$.

A β -hairpin involves two consecutive β -strands that lie antiparallel and are linked by hydrogen bonds (Fig. 1). The connecting loop region may or may not include a classical β -bend^{2,3}. To analyse the number of residues in the loop region, we used the non-subjective assignments of β -strands and coil regions given for the 62 proteins included in Kabsch and Sander's

dictionary of secondary structures⁶. Thirty-nine proteins had β -hairpins, giving a total of 107 hairpins. Loop residues (referred to as L1, L2, ...) are defined as those not participating in the antiparallel β -ladder which forms the hairpin (see Fig. 1 legend). The residues of the hairpin strands are denoted by ...-B3, -B2, -B1 for the N-terminal strand and +B1, +B2,

Fig. 3 Stereo diagrams of representative structures for the two-, four- and five-residue hairpin-loop families. *a*, Two-residue hairpin loop with a type I' β -turn; γ -chymotrypsin A, residues 201–208. *b*, Two-residue hairpin loop with a type II' β -turn; penicillopepsin, residues 198–205. *c*, Four-residue hairpin loop with a type I β -turn; penicillopepsin, residues 237–246. Note how the amide NH groups of residues L2, L3 and L4 point inwards towards the centre of the turn and to the carbonyl oxygen of the residue immediately before the loop (–B1). The side chain of this residue may help to neutralize the cluster of NH groups. Some of these bends have been described previously by Isogai *et al.*¹⁷ and Richardson¹⁶. *d*, Five-residue hairpin loop with a type I β -turn and a G1 β -bulge; γ -chymotrypsin A, residues 32–42. This structure is reminiscent of the four-residue family in that the nitrogens of residues L3, L4 and L5 all point inwards towards the carbonyl of residue L1, and an aspartyl oxygen is often observed nearby.

Sequences for two-, four- and five-residue loops. A, Sequences for those hairpins which form distinct structural families, whose ϕ , ψ values are plotted in Fig. 2. B, Sequences for the loops with miscellaneous structures. The standard one-letter amino-acid code is used. Residue numbers are taken from Cambridge Protein Data Bank Files¹⁵ given in ref. 6, except for penicillopepsin for which the more recent 2APP file was used.

* Loops with a single hydrogen bonds between the first (NH) and last (CO) residues in the loop.

+B3 ... for the C-terminal strand. Thus, a two-residue hairpin is described as (... -B3, -B2, -B1, L1, L2, +B1, +B2, +B3 ...).

The distribution of loop length in these 107 hairpins (Fig. 1) clearly shows the predominance of short loop connections, with 70% of all the observed hairpins having <7 residues in their loop regions. Even more striking is the high number of two-residue loops (29 out of 107) and to a lesser extent the four- and five-residue loops (13 and 19 observed, respectively).

The short loop β -hairpins (two-, four- and five-residue) were analysed further by plotting the main-chain dihedral angles ϕ and ψ for these loops (Fig. 2). The plots show that many of the β -hairpins fall into structural families (Table 1a), with the loop regions folded in specific ways. The two-residue β -hairpins all include one of the classic β -turn conformations categorized as types I-VIII³ (see Figs 2b, 3a, b). In a study on all the turns

found in proteins of known structure, Chou and Fasman² found that 60% were type I+III and 15% were type II (Fig. 2a). The mirror images of these two types were rarely observed, type I' constituting only 3% and type II' 5%. For hairpins, however, the types I' and II' turns predominate. Out of the 29 hairpins, 15 were type I', 10 type II' and only 4 type I. The total absence of type II turns in the hairpins and relative lack of type I turns strongly implies that these turns, which are by far the most commonly observed throughout proteins, are not compatible with an antiparallel β -hairpin. In contrast, their mirror images, which are thought to be energetically less favourable because of steric hindrance³, are clearly preferred in the context of a β -hairpin. Preliminary studies suggest that the type I' turn has the correct twist to match the relative twist which is always observed between adjacent strands⁷ (Fig. 3a). The mirror-image

type I has the incorrect twist and may therefore be unfavourable. In contrast, the types II and II' turns are relatively planar (see Fig. 3b). However, model-building two β -strands with an average twist and standard β -turns on a computer graphics system shows clearly that the types I' and II' turns give acceptable hairpins, whilst the strands rapidly diverge when a type I or II turn is included.

The sequences of the two-residue hairpins are shown in Table 1. As might have been expected from the observed ϕ, ψ plot, 12 of the 15 type I' hairpins have glycine at position L2, while position L1 is dominated by glycine, asparagine and aspartic acid (left-handed helical residues⁸). Similarly, 7 of the 10 type II' hairpins have glycine at position L1, whilst position L2 is usually the polar serine or threonine. The absence of proline is striking.

The 13 four-residue loop hairpins include various turn conformations, with the dominant grouping a family of six structures with a type I turn (Figs 2c, 3c). Four of these hairpins have a particularly similar conformation, with residues L1, L2 and L3 in the α -helical portion of the ϕ, ψ plot and residue L4 (glycine or asparagine) in the $+/+$ quadrant. The tip of these four-residue hairpins is bent over, rather like an erect hooded cobra.

The ϕ, ψ plots for the 19 five-residue loop hairpins showed clearly that one group including eight examples all adopted the same structure (Figs 2d, 3d). This may be described as a type I turn, with a hydrogen bond between the carbonyl residue L1 and the amide of residue L4, and a G1 type β -bulge⁹. This structure demands a glycine at position L4, which is observed in six of the eight sequences, with asparagine and aspartic acid in the other two (Table 1). Of the remaining five-residue loops, three include an L2(CO)-L5(NH) hydrogen bond (although the ϕ, ψ values are different) and four others have glycine at position L4, although they show no structural similarity.

One of the major aims of our study was to search for patterns to aid the prediction of hairpins from sequence. The two-residue loops are strongly selective for amino-acid type. For a type I' turn, L1 = Asn, Asp, Gly; L2 = Gly; for a type II' turn, L1 = Gly and L2 = Ser, Thr or polar. The four- and five-residue loop families have a weaker preference for glycine at position L4. The other residues are usually hydrophilic, as expected for an exposed loop, and often include the classical turn-forming residues.

There is also evidence for distinctive patterns in the residues on either side of the hairpin loop. In addition to the usual alternation of hydrophobic and hydrophilic residues, a matching of residue types across the hairpin is observed. Thus, residues +B3 and -B3 are usually both hydrophobic or both hydrophilic (80% of sequences in Table 1), similarly residues +B2 and -B2 (67%). Such paired residues point in the same direction and are usually therefore in a very similar environment.

These patterns are being incorporated into our template prediction algorithm, which aims to recognize β -hairpins rather than just β -strands. Currently, for the β family of proteins, we

obtain an ~8% improvement in prediction accuracy over the conventional secondary structure prediction algorithms. This is similar to the improvement obtained for the $\beta\alpha\beta$ proteins⁵.

Our results show that the irregular coil regions connecting secondary structures in proteins may include structural and sequence patterns. This limited survey of β -hairpins indicates that the short loop hairpins are highly selective in sequence and can provide a valuable aid to *ab initio* prediction and model-building studies. Insertions and deletions most commonly occur in the loop regions of proteins¹⁰, so that prediction of an unknown structure by homology to a known structure becomes a problem of building the loop regions (for example, renin¹¹). We are currently studying the longer loops and homologous β -hairpins to determine the effects on loop conformation.

In the β -sandwich structures there are essentially only two types of connections between β -strands—a β -hairpin between adjacent H-bonded strands and β -arch between strands on opposite sheets crossing the top of the sandwich. In terms of chain topology, it is critical to differentiate a β -arch from a β -hairpin. Although this will clearly depend largely on the amino-acid composition of the strands (for example, very hydrophobic strands will occupy central positions in the sheet¹²), the sequence of the connecting loop may also be influential. Preliminary studies of β -arches show that their length distribution is grossly different from that of β -hairpins, with a peak for the eight-residue loop. Sequence patterns may also be found for connections between helices^{13,14} and between strands and helices in the $\beta\alpha\beta$ unit. With such information on the loop regions of proteins, the prediction of structure from sequence by template and pattern recognition methods becomes very attractive.

We thank Chris Sander for making the secondary structure dictionary available to us before publication; also Tom Blundell for encouragement and enthusiasm and Michael Green, Mike Sternberg, Willie Taylor and David Barlow for useful discussions.

August meeting

21–23 August 1985, **International Workshop on Molecular Biosciences and Bio technology**, Madras, India (Convenors of the workshop, SPIC Main Office, 97 Mount Road, Madras-600 032, India).

September meetings

15–20 September 1985, **International Symposium on Renal Basement Membranes**, London, UK (Dr R. G. Price, Biochemistry Dept., Queen Elizabeth College, Campden Hill Road, London, W8 7AH, UK).

16–20 September 1985, **International Basement Tectonics Conference**, Santa Fe, New Mexico, USA (M. Aldrich, General Chairman, Mail Stop D462, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA)

November meeting

21–22 November 1985, **First International Conference on Protein Engineering**, London, UK (Miss H. Raquet, Oyez Scientific and Technical Services Ltd, Bath House, 3rd Floor, 56 Holborn Viaduct, London, UK).

Appointments

Dr Robert Sharpe has been appointed director of the Lord Dowding Fund for Humane Research, in succession to the late Bernard Conyers. The fund actively promotes the development of viable alternative techniques to the use of living animals for research and testing.

Professor John L. Jinks, Vice-Principal of Birmingham University, has been appointed to the board of directors of the Agricultural Genetics Co. Ltd (AGC), the Cambridge-based biotechnology company.

Four new members have joined the Imperial Cancer Research Fund Council. They are **Professor Robert Mahler**, Consultant Physician at Northwick Park Hospital; **Sir John Vane**, Group Research and Development Director, The Wellcome Foundation; **Professor John Evans**, Director of the MRC's Clinical Population Cytogenetics Unit; and **Professor David Weatherall**, Nuffield Professor of Clinical Medicine at the University of Oxford.

Dr J. W. Almond, lecturer in microbiology at the University of Leicester, has been appointed Professor of microbiology at Reading University.

Reading University has appointed **Dr D. L. Pyle** as Professor of biotechnology. He is currently at the Imperial College of Science and Technology, University of London.

The Heriot-Watt University has announced two new professorships. **James L. Murray** has been appointed to a new Chair of Computer-Aided Engineering in the department of mechanical engineering—with effect from 1 May 1985, and **John A. Swaffield** has been appointed to a new Chair of Building Services Engineering in the department of building—from 1 September 1985.

Dr P. G. Hare, at present reader in economics at the University of Stirling, has been appointed Professor of economics at Heriot-Watt University, Edinburgh.

Raymond E. Wetton, Chairman of Polymer Laboratories Ltd, has been appointed Visiting Professor in the department of chemistry at Loughborough University.

Richard K. Root, Professor and vice-chairman of the department of medicine at the University of Washington, has been named the new chairman of the University of California, San Francisco Department of Medicine.

The following have been elected to the Fellowship of Imperial College, London: **Emeritus Professor J.H. Argyris**, Imperial College and University of Stuttgart; **Mr John Egan**, Chairman and Chief Executive, Jaguar Cars Ltd; **The Rt Hon Lord Carr of Hadley**, Chairman, Prudential Corporation and Prudential Assurance Company, Governor, Imperial College; **Mr H.M. Neal**, Chairman, City and Guilds of London Institute; **Professor Sir Randolph Quirk**, Vice-Chancellor, University of London; **Emeritus Professor J. Sutton**, Senior Research Fellow, Centre for Environmental Technology at Imperial College.

Awards

The Simon-Fraser University R. H. Wright award in Olfactory Research has been made to **Professor Karl-Ernst Kaissling** of the University of Seewiesen, FRG. He was cited for his pioneering work in the understanding of the process of olfaction (the sense of smell).

The Royal Society of Chemistry and the Society of Maccabaeans have named the joint winners of this year's Meldola Medal and Prize. **Dr James Darwent**, lecturer in chemistry at Birkbeck College, London, and **Dr Ian Rothwell**, assistant Professor at Purdue University, Indiana, USA, will each receive a bronze medal and £100. The award is made annually to the most promising British chemist under the age of 30.

Dr Mary F. Lyon, FRS, Deputy Director and Head of Genetics Division at the MRC Radiobiology Unit in Oxfordshire has been awarded the 4th Sanremo International Prize for genetic research.

A multidisciplinary team led by **Professor Ronald J. Roberts** at the Institute of Aquaculture, University of Stirling, UK, has been nominated by the British Government for this year's UNESCO Science prize. The nomination recognizes the work of the team on the development of an intensive culture system for farming Tilapia. This is the most important farmed fish of Africa and South-East Asia, which is making an increasing contribution to protein availability in developing countries.

The North Jersey Section of the American Chemical Society has announced that **Alexandra Pines**, Professor of Chemistry at the University of California, Berkeley, has been selected to receive the 1985 Leo Hendrick Baekeland Award. The award, sponsored by Union Carbide Corporation, is made in recognition of his work in the field of magnetic resonance.

Applications are invited for the MRC Senior Fellowships (nonclinical), to arrive before 30 September 1985. The scheme is intended to provide support for a small number of outstanding scientists, and covers personal support for initially the first six years, with provision for supporting staff/expenses/equipment for the first three years. Applicants should be untenured, but with no less than three years' postdoctoral research experience at the date on which they would take up their fellowship. Applicants should be between the ages of 26 and 32 (inclusive) on 30 September 1985, and can obtain further information from the Grants Section at MRC's Headquarters Office (MRC, 20 Park Crescent, London W1N 4AL, UK).

The International Union Against Cancer will award "International Cancer Research Technology Transfer" grants for research on cancer. The purpose of the programme is to promote the transfer of information about new or improved techniques or methods in areas of basic, clinical or behavioural research, in order to further the progress of cancer research. The available funds will permit researchers of any nationality to visit a research centre, or centres, abroad for a period not exceeding 28 days. Information and application forms can be obtained from: International Union against Cancer, Rue du Conseil-General 3, 1205 Geneva, Switzerland.

Miscellaneous

The Voluntary Licensing Authority (VLA) for human *in vitro* fertilization (IVF) has been set up by the Medical Research Council and the Royal College of Obstetricians and Gynaecologists. Centres offering an IVF service or undertaking research in this field may apply to the authority for approval of their work.

CANCELLATIONS MUST BE RECEIVED NO LATER THAN 5 p.m. ON THURSDAYS PRIOR TO ISSUE DATE.

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

TUTORIAL FELLOW

Applications are invited from graduates for the above post. Salary range £6,600 — £7,055 per annum. The post is for three years commencing in October. The appointee will have a First or Upper 2nd Class Honours Degree and will be permitted to register for a PhD. There will be some limited teaching duties and the appointee will join Professor K.S. Dodgson's research group in studies on the biodegradation of surfactants and other industrially important compounds.

Applications (2 copies), together with the names and addresses of two referees should be forwarded to the Establishment Officer, University College, PO Box 78, Cardiff, CF1 1X, from whom further particulars are available. Closing date 31st July, 1985. Ref: 2978. (7062)A

THE UNIVERSITY OF BRISTOL

DEPARTMENT OF
VETERINARY MEDICINE

Applications are invited for a POSTGRADUATE RESEARCH ASSISTANT (Range 1B)

to work on the Immunology of the gastrointestinal tract of horses. The successful candidate will join a multi-disciplinary group investigating responses to microbial and dietary antigens and would be expected to register for a higher degree. The post funded for three years by the Horse-race Betting Levy Board is open to veterinary and biological science graduates. Starting salary: up to £7,980 per annum.

Applications should be sent enclosing a curriculum vitae and details of two referees to Professor F J Bourne, Department of Veterinary Medicine, Langford House, Langford Bristol, BS18 7DU, by 22 July 1985. (7061)A

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF BIOCHEMISTRY
POST-DOCTORAL FELLOW

Applications are invited for a research fellowship financed by the British Heart Foundation for a study of phosphoinositide metabolism and the molecular mechanisms mediating the responses of cardiac muscarinic receptors. The fellowship is tenable for two years initially from 1st October, 1985 at a starting salary of £7,980 or £8,450 depending on age and experience. Membership of USS included

Applicants should send curriculum vitae and the names of two referees to Professor J N Hawthorne, Department of Biochemistry, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, from whom further details may be obtained (telephone: 0602-700111 Ext 3488). Closing date 31st August, 1985 (7065)A

UNIVERSITY OF LIVERPOOL

DEPARTMENTS OF IMMUNOLOGY
AND BIOCHEMISTRY

Applications are invited for the post of Senior Research Assistant in the Department of Biochemistry to work on an investigation into gene cloning of human oncotrophoblast antigens defined by monoclonal antibodies. This work has important implications for our understanding of materno-foetal interactions as well as the process of oncogenesis. This is a post-doctoral position for which experience in recombinant DNA techniques would be a strong advantage.

Initial salary within the range £7,520 — £8,920 per annum

Applications, together with the names of three referees, should be received not later than 26 July 1985 by the Registrar, The University, PO Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/14 (7074)A

Clinical Research Associates

Up to £16,000 pa + profit sharing

ICI Pharmaceuticals Division has opportunities for a number of highly motivated Clinical Research Associates to join the headquarters of a dynamic international business.

Set in 400 acres of beautiful parkland, within a few miles of an international airport, the M6 and the city of Manchester, the Division has earned a reputation for innovation and technical excellence. It has received no less than 10 Queens Awards to Industry for Technological Achievement and Export.

Due to an expansion in our medical function we are now seeking to recruit several CRA's who will enjoy the challenge and rewards of operating in this highly successful environment.

Successful candidates will be able to meet the following requirements:

- Good interpersonal skills.
- Experience of planning, progressing and servicing clinical studies.
- A sound knowledge of Human Physiology and an understanding of disease processes.
- A degree or equivalent qualification in a biological discipline.

In addition to a very competitive salary we offer excellent conditions of employment, good technical and recreational facilities and assistance with relocation where appropriate.

Applications enclosing a detailed CV should be addressed to:

Miss J E Huckvale, Personnel Officer,
Imperial Chemical Industries plc,
Pharmaceuticals Division,
Mereside, Alderley Park,
Macclesfield, Cheshire. SK10 4TG.

INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS

needs

A Groundnut Breeder at Niamey, Niger

To initiate and develop a regional groundnut breeding program in West Africa in conjunction with a groundnut pathologist and as part of a multidisciplinary regional team whose objective is to develop high-yielding stable varieties of groundnut suitable for use in farming systems of the region and to develop materials with resistances to the main biotic and abiotic constraints presently limited production, in particular drought, leaf spots, and rosette.

The Groundnut Breeder will conduct in cooperation with national programs of the region, multilocal yield trials and nurseries and supply cooperators with breeding materials; work with national programs to develop their effective capability for the improvement of groundnuts including periodic training programs; contribute to the development of a regional groundnut research network, and evaluate and maintain germplasm both local and exotic for desirable characters. Cooperate closely with the ICRISAT Center program and ICRISAT's regional program in southern African, in multilocal evaluation and selection to develop widely adapted parental material. A Ph.D. in plant breeding with five years experience in breeding groundnuts or related crops, ability to work with national and international scientists from a range of disciplines, and to travel frequently to conduct research in the groundnut growing areas of West Africa are essential. He should have excellent command of English. Working knowledge of French and experience in tropical agricultural research particularly in semi-arid environments are desirable.

A Groundnut Pathologist at Niamey, Niger

To work as part of a multidisciplinary regional team to develop for the limited-resource farmer high-yielding and stable varieties of groundnut, to insure that such varieties carry adequate epidemics, and to conduct research that will contribute to enhanced knowledge and understanding of groundnut diseases in the region. The pathologist will develop a research program on diseases of groundnut, both fungal and viral, in West Africa in cooperation with a groundnut breeder and other disciplines and will cooperate in screening materials and in the establishment of regional testing networks and training programs. A Ph.D. in plant pathology with several years' experience in the field of host plant resistance, ability to work with national and international scientists from a range of disciplines, and to travel frequently to conduct research in the groundnut growing areas of West Africa are essential. He should have excellent command of English. A working knowledge of French, and experience in tropical agricultural research particulars in a semi-arid environment are desirable.

The positions are on a 3-year contractual basis with possibilities of further extension. The posts are located at the ICRISAT Sahelian Center near Niamey, Niger, which is the regional headquarters for ICRISAT's West African programs. Niamey, the capital city, has good living conditions, international airline connections, and educational facilities for children in French and English.

Send résumé and names and addresses of three referees within 60 days of the date of the advertisement to the Director General, ICRISAT, Patancheru P.O., Andhra Pradesh 502 324, India.

THE UNIVERSITY OF BERGEN

invites applications for a vacant chair in

SOLID EARTH PHYSICS (MARINE GEOPHYSICS)

Salary is on the scale 33, Nkr 233,752, p.a. gross, of which Nkr 4,010 p.a. are paid in pension contributions.

The chair will be appointed on the understanding that any changes in scientific duties, pension or retiring age made by law or by the King with the agreement of Parliament are to be accepted without compensation.

Applicants should submit 5 copies of scientific work — published or unpublished — which they wish to be considered for the appointment as well as 6 copies of a list of all scientific contributions with information on where they were published. Scientific contributions are to be submitted, in numbered order an in 5 groups, to the science faculty of the University of Bergen within one month of the closing date for applications. Scientific manuscripts in preparation may be submitted within 3 months of the closing date for applications provided notice of intent is given on submitting the other publications. Applicants are otherwise referred to the current rules for the procedure to be followed in the appointment of professorships and readerships. A résumé of the vacant chair can be obtained on request from: Sekretariatet for Det matematisk-naturvitenskapelige fakultet, Postboks 25, 5014 Bergen-Universitetet, Norway.

Applications, which must include a complete curriculum vitae, should be addressed to the King and be sent together with relevant certificates and one copy of a list of publications to Det matematisk-naturvitenskapelige fakultet, Postboks 25, 5014 Bergen-Universitetet, within Oct, 1985. (W2020)A

BILLERICAY BURNS RESEARCH TRUST SENIOR RESEARCH FELLOW

Applications are invited for a Senior Research Fellow for a project in burns research. Considerable experience in independent research will be required. The Fellow will be expected to pursue not only his own project but also to give advice to guidance on their research projects to surgical staff at this Regional Centre for Plastic Surgery and Burns.

The Fellow's research project might be in the structural, biochemical, pharmacological, physiological or experimental pathological fields.

It is envisaged that the Fellow would be of a status such as would enable the Trust to seek for him or her an honorary university appointment in one of the University of London Medical Schools.

Further details may be obtained from:

A. F. Wallace, F.R.C.S.
N.E. Thames Regional Plastic Surgery Centre,
St. Andrew's Hospital,
Billericay,
Essex.

(7082)A

THE DEPARTMENT OF PHYSIOLOGY University of Manitoba

invites applications from young investigators in the field of

CARDIOVASCULAR PHYSIOLOGY

to be appointed at the level of Assistant Professor

The successful candidates will be expected to compete for local and national scholarship awards and develop their independent research programs. Applicants with backgrounds in membrane transport, electrophysiology, molecular biology or hemodynamics are encouraged to submit their curriculum vitae, an outline of their research interests as well as to arrange for three letters of reference to be sent to Dr. Henry G. Friesen, Professor and Head, Department of Physiology, Faculty of Medicine, University of Manitoba, Winnipeg, Manitoba, R3E 0W3 Canada. Deadline for application is 2 September 1985. The University of Manitoba is an Equal Opportunity/Affirmative Employer, but in accordance with Canadian Immigration, priority will be given to Canadian citizens and permanent residents of Canada. (NW12)A

INTERNATIONAL INSTITUTE FOR AEROSPACE SURVEY AND EARTH SCIENCES

The ITC is concerned with international scientific education, research and consulting in aerial photography and teledetection, photogrammetry, aerospace survey application in land resources studies, agriculture, earth sciences, human settlements, geo-data processing and cartography, in particular directed towards the needs of developing countries.

GIS/LIS SPECIALIST

We are searching for a person with an appropriate higher degree and substantial work experience in geo- and land information systems.

The responsibilities include:

- teaching at the post-graduate level, particularly in a new one year diploma course in LIS
- initiating and undertaking research
- coordinating the research activities of an inter-disciplinary group in geo-information systems
- acting as a consultant to projects.

Some foreign travel can be expected.

The Institute is placing increasing emphasis on the development of geo-based and land information systems. It is supported by excellent facilities in aerial photography, photogrammetry, remote sensing, image processing, cartography, natural resource inventories and human settlement analysis. Currently these include aircraft, analytical plotters, image processing and interactive graphic systems, scanners and plotting devices.

GIS/LIS an area of growth in this Institute. The person appointed will be expected to play a key role, and can anticipate a rewarding career.

For further information make early contact with the rector of the Institute, Prof.dr.ir. K.J. Beek, if preferred by telephone; formal applications should be addressed to the Head of Personnel & Organisation.

350 Boulevard.1945,
P.O. Box 6
7500 AA Enschede
The Netherlands.
Phone 903153-320330.

In addition to this particular post, the Institute is always interested in receiving curriculum vitae's from persons, within the fields mentioned above who are available for both short and long term appointments in the Netherlands and/or abroad.

GUINNESS

RESEARCH SCIENTISTS

Guinness is expanding its product range which it sells worldwide. The Company's Worldwide Research Centre based at the St James's Gate Brewery in Dublin is the focus of new product development for the Guinness Group, both in Ireland and internationally, and wishes to expand its expertise in this area.

Applications are invited therefore from Research Scientists/Technologists to work in the areas of flavour chemistry and new product development. A Ph.D. qualification and/or equivalent research experience in food science technology or related topics is essential but previous experience in brewing is not necessary.

The excellent benefits package provided will include a highly competitive salary, non-contributory pension, profit share, free lunch and medical benefits. Starting point will be related to previous experience and qualifications.

Applications containing CV details should be sent to

Dr. A. J. Forage
Manager, Guinness Research Centre
St. James's Gate
Dublin 8 Ireland.

by 26 July 1985.

(7102)A

BIOCHEMIST/ MOLECULAR BIOLOGIST

The Department of Biochemistry and Biophysics is seeking applications for two Assistant or Associate Professorships. These are 12 month, tenure track positions jointly funded by the College of Agriculture and the Texas Agricultural Experiment Station. Outstanding individuals having research interests dealing with the molecular aspects of regulation, structure, mechanism or function in microbial, animal or plant systems are sought. In addition to research, participation in the department graduate and undergraduate teaching programs will be required. A terminal degree in either biochemistry or a related field plus appropriate postdoctoral experience is required.

Applicants should send a curriculum vitae, list of publications, a brief description of current and future research directions, and names of three references to:

Dr. E. G. Sander, Head
Department of Biochemistry and Biophysics
Texas A&M University
College Station, TX 77840-2128

Applications will be accepted until October 15, 1985, or until suitable candidates are found.

The Texas A&M University System is an Affirmative Action/Equal Opportunity employer.

(NW76)A

THE IRISH EQUINE CENTRE DIRECTOR/ SCIENTIFIC DIRECTOR

The Irish Equine Foundation Limited invites applications for the post of Director/Scientific Director of the Irish Equine Centre. The Irish Equine Centre is located at Johnstown, Naas, County Kildare, Ireland and is engaged in the investigation, diagnosis and research into equine diseases. Phase 1 in the development of the Centre includes departments of pathology, bacteriology, virology and immuno-haematology.

Applicants should have a registrable veterinary qualification. The successful candidate will have a doctorate or its equivalent, a distinguished research career and promise of administrative skills to provide leadership and co-ordination of a diverse group.

Salary, which will not be less than IR£35,000 per annum, and other benefits will be commensurate with the responsibilities of the position and dependent on experience.

Closing date for applications is September 20th 1985.

Applicants should include a full Curriculum Vitae and the names and addresses of two referees who will be contacted only with the prior permission of the applicant.

On behalf of the Board of Governors, Irish Equine Centre, P.W. McGrath, LL.D., Chairman.

Applications should be submitted to the Secretary, The Irish Equine Foundation Limited, Irish Equine Centre, Johnstown, Naas, Co. Kildare, Ireland. (7075)A

MERRELL DOW RESEARCH INSTITUTE

STRASBOURG-CENTER

We are part of the Merrell Dow Research Institute. Our Center located in Strasbourg is dedicated to apply basic research to discover new therapeutic leads. We are looking for two

BIOCHEMISTS

(Ph.D. + 1 or 2 year postdoctoral experience at least) to join our multidisciplinary research team.

The first position requires interest and proven skill in all aspects of enzymology (purification, assay, modification, etc.).

The second position is offered to a young biochemist with a strong background in organic chemistry, more oriented towards mechanistic approaches.

Essential personal qualities are initiative, creativity and ability to collaborate with other scientists within our team.

If you are interested in these positions, please send C.V. with names of 3 referees we may contact to:

M. J. Bildstein
Personnel Department
Merrell Dow Research Institute
16 rue d'Ankara
67084 Strasbourg Cedex.

(W2031)A

UNIVERSITY OF OXFORD
Department of Biochemistry
POST-GRADUATE
RESEARCH ASSISTANT —
1B

(Ref: BC/131)

A Research Assistant Grade 1B is required to work in the Eukaryotic Gene Expression Group of Drs. A.J. and S.M. Kingsman. Experience in microbial genetics or recombinant DNA and/or mammalian cell culture procedures would be an advantage.

The appointment is for three years and will be made on the Scale £6,600 — £10,330 p.a., depending upon age and qualifications.

Applications, including the names and addresses of two referees should be sent, by 31st July, 1985 to:

**The Administrator,
 Department of Biochemistry,
 South Parks Road,
 Oxford OX1 3QU. (7071)A**

**RESEARCH TRAINING IN
 SALIVARY SECRETION**

Positions available starting summer 1985 at the University of Washington for research training in the biochemistry, cell biology, microbiology, physiology, pharmacology and/or pathology of salivary secretion. Applicants should have Ph.D. or professional degree (M.D., D.D.S., D.V.M., or equivalent) and must be U.S. citizens or have permanent visas.

Graduate programs leading to Ph.D. or M.S. are available. Stipends: \$15,996 to \$30,000, depending upon exercise.

Send curriculum vitae, three references and statement of research interests to: Dr Kenneth Isutsu, Department of Oral Biology SB-22, University of Washington, Seattle, Wash. 98195 at earliest possible date.

An Affirmative Action Equal Opportunity Employer.

ONCOGENE SCIENCE INC.

Expanding staff at Long Island, NY research facilities due to advances in

Oncogene and growth factor research
 to develop products for the early
detection -- monitoring -- treatment
of human cancers.

— Positions Available —

DIRECTOR OF BIOCHEMISTRY

Responsible to direct and coordinate corporate biochemistry program. Ph.D. in Protein Chemistry — purification and sequencing; 8-10 years postdoctoral experience. Strong publication record highly desirable. Will contribute to development of diagnostic and pharmaceutical products.

PROJECT DIRECTOR

Responsible for formatting diagnostic tests for HTLV-III infection and oncogene activation. Test development, pilot and scale-up operations, standardization of appropriate QC procedures. Ph.D. in Immunochemistry. 5-7 years postdoctoral experience in immunoassay, format design, product development.

MOLECULAR BIOLOGIST

To participate in projects aimed at determining the role of oncogenes in human cancer using cDNA cloning, *in situ* hybridization and bacterial expression of antigens. Ph.D. in Molecular Biology, although candidates with Masters degree and appropriate experience will be considered.

Be part of the excitement at OSI.

Send resume and personal data to Scientific Director,
 Oncogene Science Inc., 222 Station Plaza North, Suite 330,
 Mineola, NY 11501.

Competitive salary. Liberal benefits.
Equity potential.

Equal Opportunity Employer

(NW31)A

PATHOLOGIST

Experimental and/or Comparative

Requirements: M.D., D.V.M., or Ph.D. in Pathology Board Certified or eligible.

Duties: Research and diagnostic service in a comprehensive pathology laboratory in a large, modern research facility. Independent research in one or more areas of interest, as well as collaborative studies with departmental research staff. Diagnostic service will involve human and animal pathology if applicant holds an M.D. Facilities for morphologic studies are excellent, including quantitative light microscopy, TEM, SEM and high-voltage electron microscopy. The Wadsworth Center has ongoing programs in every area of basic and applied biomedical science, clinical and environmental.

Salary: Open, dependent on degrees, certification held and experience.

Send résumé to: Doris N. Collins, M.D., Wadsworth Center for Laboratories and Research, New York State Department of Health, Empire State Plaza, Albany, NY 12201. (NW17)A

Colaiste na hOllscoile Corcaigh

UNIVERSITY COLLEGE CORK

BIOCHEMISTRY DEPARTMENT

Applications are invited for a full-time temporary appointment at the level of Assistant Lecturer or College Lecturer in the Department of Biochemistry. The appointment, which will commence on 1 October, 1985, will be for one year in the first instance with the possibility of extension for two further years. Applicants should preferably have research experience in protein or nuclear acid biochemistry, but candidates with research experience in other fields will be considered. The salary will be within the range IR£10,432 to IR£14,179 depending on experience.

Candidates should make a written application, including the names of two referees, to reach the undersigned not later than Friday, 16 August, 1985. Professor S. Doonan, Head of Biochemistry Department, University College, Cork, Ireland.

(NW16)A

THE UNIVERSITY OF NEW SOUTH WALES
Sydney, Australia

INDUSTRIAL LASER PHOTOCHEMISTRY

SENIOR RESEARCH SCIENTIST, RESEARCH SCIENTIST, POSTDOCTORAL

Applications are invited for several positions in a research group which is developing laser-based industrial photochemical processes. Experience in lasers, photochemistry, optical spectroscopy and industrial applications would be helpful.

The University of New South Wales contracted with the Commonwealth of Australia to work intimately with the Australian chemical industry to develop new commercial processes using lasers. Successful candidate processes are to be taken to the pilot plant design stage.

Since July, 1984, funding of A\$1 million has been used to set up a laboratory including four excimer lasers, pulsed dye and CW ring dye lasers, and a Fourier Transform UV-IR Spectrometer. A further A\$1 million has now been contracted to provide for additional staff and equipment. Appointments will be for one year, with possibilities of continuing depending on additional funding. Sabbatical or postdoctoral applicants are welcome.

Work involves investigation of scientific feasibility of proposed processes, optimization studies, small-scale reactor tests, followed by preparation of estimates for prototype production plants. Already one pilot plant design has been submitted to the government for additional funding and a second pilot plant is under discussion with the company involved. Funding is available for patents, and two worldwide patents have been submitted.

In addition to working with state-of-the-art equipment and collaborating with industry on real-world problems, applicants will have the opportunity of working with a Project Technical Leader of international stature. Industrial liaison is handled by the Project Manager. Project staff will collaborate with workers from industry who are associated with the six processes being investigated. Applicants will be expected to be technically strong, and opportunities exist for publication in the open literature.

Salaries will be commensurate with experience, and will be up to A\$38,700. Applications close September 15. Appointees will be expected to commence work as soon as possible, and no later than January 1, 1986.

Call Dr George Paul, Project Manager (612) 697-4586, (612) 419-5865 (home). Telex UNREG AA26054. Or write Dr. Paul, School of Physics, University of New South Wales, Kensington, NSW 2033, Australia.

EQUALITY OF EMPLOYMENT OPPORTUNITY IS UNIVERSITY POLICY.
(W2032)A

FACULTY POSITIONS IN ELECTRICAL ENGINEERING (SOLID STATE DEVICE AND MICROELECTRONICS AREA)

The Pennsylvania State University at University Park, Pennsylvania invites applications for tenure track faculty positions at the Assistant Associate and Full Professor ranks in Electrical Engineering in the area of Solid State Device and Microelectronics. Applicants should have an earned doctorate in electrical engineering, engineering physics or related fields, and have demonstrated the ability to conduct research and teaching in the field of Solid State Device and Microelectronics.

The successful candidates are expected to join the existing effort in the solid state device research and help develop it into one of prominence. The College of Engineering has made substantial commitments to support this program by hiring of an endowed professor in this area.

Currently, research in the solid state device and related materials area includes research in silicon device processing, such as plasma and reactive ion etching, thermal nitridation of silicon and various oxide research including ultra-thin oxides, and defect control. In addition, research in III-V device area includes material defects, electrical noise and performance improvement of micron and sub-micron structures.

Combined research in the solid state device area typically amounts to about one million dollars annually. Collaborative research opportunities exist with the Materials Science department, Engineering Science and Mechanics department, the Chemistry and the Physics departments and the Materials Research Laboratory at Penn State.

Resumes, or inquiries should be directed to the following address by no later than September 15, 1985, or until suitable candidates are identified.

Indiana University is an Equal Opportunity/Affirmative Action Employer (NW37)A

In the course of the expansion of our research effort in the animal health field we are establishing a new R+D unit in

ANIMAL HEALTH BIOTECHNOLOGY

The new unit will be responsible for the preclinical and clinical development of biotechnological derived materials, and will concentrate its efforts in the areas of **NONSPECIFIC IMMUNITY AND GROWTH/PRODUCTIVITY**.

Our organization is committed to establishing and maintaining a highly competitive R+D program in these areas with the ultimate goal of providing novel practical solutions to problems in Animal Health.

As members of our new team we are now seeking several highly qualified Ph.D. or DVM level scientists experienced within the following areas:

- **VIROLOGY**
(Cultivation and biology of viruses affecting livestock)
- **MICROBIOLOGY/PARASITOLOGY**
(Cultivation, biology and immunology of intracellular pathogens affecting livestock)
- **IMMUNOBIOLOGY**
(Immunological methodology, host-pathogen interactions, non-specific immunity)
- **GROWTH PHYSIOLOGY/ENDOCRINOLOGY**
(Hormonal and nutritional factors affecting growth, *in vitro* and *in vivo* test methodology)
- **PHARMACOLOGY**
(Pharmacology of proteins and peptides, immuno-pharmacology, analytical methodology)
- **FORMULATION AND DELIVERY**
(Experimental formulations of proteins, slow release devices, liposomes, adjuvants)
- **PROTEIN BIOCHEMISTRY**
(Isolation and characterization of proteins, recovery process development and scale up, analytical methodology)

Candidates with appropriate qualifications and experience will be considered for group-leader positions.

The new unit will be housed in a separate laboratory building on our Research Station in Switzerland and will profit from the extensive infrastructure and the animal facilities available. The group will engage in collaborations with various internal R+D units, with academic institutions and with leading biotechnology companies worldwide.

Prospective members of the team should bring a solid scientific basis, the capability to function creatively in a highly interactive environment and the willingness to contribute to the solution of practical problems in animal health care.

Applications will be kept confidential and should include curriculum vitae, a list of publications and at least two references.

Please direct your application to Mr. H. Gerber, CIBA-GEIGY LTD., Personnel Department, CH-4002 Basel, Switzerland.

**DIRECTOR OF MANUFACTURING
FERMENTATION OPERATIONS
BIOTECHNOLOGY**

Israeli Subsidiary of Public U.S. Company

We have been retained by one of the world's leading biotechnology companies to conduct a search for a seasoned Director of Manufacturing from the pharmaceutical or biotechnology industries. Employing genetic engineering and related technologies, our Client is poised to commercialize up to 5 products in the areas of human health care, animal health care and plant agriculture, and has entered into licensing agreements with 3 well-known multi-national pharmaceutical companies. The individual selected for this outstanding growth opportunity must have a strong background in fermentation and protein process manufacturing and will likely be the number 1 person in charge of production at a state-of-the-art facility. The successful candidate will immediately inherit a pilot manufacturing operation of 18-20 supervisory and production personnel and be the key individual leading a design team responsible for scaling up to full manufacturing operations. Quality control and control of the bottom line are both of paramount importance to our Client.

The successful candidate will report directly to the President of the Company and work closely with R&D. A bachelor's degree (master's preferred) in Chemistry, Chemical Engineering or Biology would be a distinct plus. The company offer includes an excellent salary and incentives package.

Please forward your resumé or curriculum vitae, with salary history to:

**Research Scientist,
Herbicides**

Agriculture Canada
Canadian Forestry Service
Northern Forest Research Centre
Edmonton, Alberta

We require an experienced scientist to conduct research programs related to the effective and environmentally acceptable use of herbicides for vegetation management. You will provide scientific direction on the use of herbicides for vegetation management in forest ecosystems, and interpret research results to enhance understanding of herbicide residue chemistry, persistence, movement and degradation in selected forest soils under controlled and field conditions. It will be your responsibility to generate scientific knowledge and environmental data as needed.

You require graduation with a doctoral degree from a recognized university, or a lesser degree with evidence of research experience and productivity equivalent to that of a doctoral degree in plant science with specialization in herbicide chemistry and biology. It is essential that you possess experience in herbicide residue chemistry (including the use of gas chromatographs, mass spectrometers and other analytical procedures), as well as in biology and related environmental impact issues. Knowledge of English is essential.

We offer a salary ranging from \$28,176 to \$52,409 commensurate with your qualifications and experience.

Forward your application form and/or résumé, quoting reference number S-85-31-5467-47JG-(G27), to:
Joan Girling (613) 996-8054

The University of Texas at Austin

Department of Zoology

PROFESSOR AND CHAIRMAN

The Department of Zoology of the University of Texas at Austin invites applications or nominations for a departmental Chairmanship to be occupied in September of 1986. The Department of Zoology is multi-disciplinary in scope and includes research interests ranging from molecular biology to evolutionary ecology. Specific research interest of the applicant is not of great concern, but an appreciation for the breadth and integration of such diverse biological disciplines, and a strong personal research program is deemed important. Some administrative experience is preferred. Applicants should send a curriculum vitae, a letter elaborating upon research and administrative goals, and the names and addresses of four references to:

Dr F. H. Bronson
Department of Zoology
University of Texas
Austin, Texas 78712

The deadline for applications is November 1, 1985.
 The University of Texas at Austin is an Equal Opportunity/ Affirmative
 Action Employer. (NW35)A

**Assistant or Associate Professorship in
Cardiovascular Pharmacology**

The Stritch School of Medicine, Loyola University of Chicago, is seeking to fill a tenure track position with a cardiovascular pharmacologist. The successful candidate will have a Ph.D. and/or degree, post-doctoral experience, and a capability to develop a productive, independent basic or clinical cardiovascular pharmacology research program.

The Stritch School of Medicine is located in a near-West suburb of Chicago, and has established programs in cardiovascular physiology, cardiac electrophysiology, hematopharmacology, neuropharmacology, and cardiology.

Candidates should send their CV, three letters of recommendation, representative reprints, and a synopsis of their current and future research interests to:

Dr. S. A. Lorens
Department of Pharmacology
Loyola University Medical Center
2160 South First Avenue
Maywood, Illinois 60153
Tel: (312) 531-3261

The deadline for applications is October 1, 1985.
 Loyola University is an Equal Opportunity Employer (NW25)A

THE UNIVERSITY OF ALBERTA
invites applications for the
CANADIAN PACIFIC — ALBERTA
AGRICULTURE CHAIR IN PLANT
BIOTECHNOLOGY

The University of Alberta is seeking an established scientist to occupy the Canadian Pacific — Alberta Agriculture Chair in Plant Biotechnology. The occupant of the chair will be expected to carry out research related to the improvement of agriculture in Western Canada, to provide leadership within the area of plant biotechnology in the Faculties of Agriculture and Forestry, and Science, and to communicate actively with the agricultural sectors of industry and government. Candidates presently located outside the scientific university community will be given serious consideration, although scientific credentials will be of paramount importance.

The successful candidate will be a member of the Department of Plant Science, in the Faculty of Agriculture and Forestry. The Faculty of Agriculture and Forestry has ninety academic members housed in a modern, well-equipped research complex. In addition, within the Faculty of Science, members of the Departments of Botany, Genetics, and Microbiology are currently involved in basic and applied plant research. The University of Alberta (approximately 25,000 students) is located in the capital city of Alberta. Please send curriculum vitae, names and addresses of at least three referees, and an outline of research interests, including reprints of relevant publications, to:

Dr. Mary Spencer
Department of Plant Science
Faculty of Agriculture and Forestry
University of Alberta
Edmonton, Alberta T6G 2P5
Canada

Closing date for receipt of applications is August 31, 1985. Salary will be by negotiation. Appointment will commence on January 1, 1986, or as soon as possible thereafter.

The University of Alberta is an equal opportunity employer but priority will be given to Canadian citizens and permanent residents of Canada. (NW19)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
RESEARCH ASSISTANT
MOLECULAR BIOLOGY

A graduate in Biochemistry or Chemistry with a good honours degree is sought for a research assistantship in the laboratory of Dr David Lilley. The person appointed will join a very active research group working on DNA structure, DNA supercoiling and their relevance to gene expression.

The work will involve chemical synthesis of oligonucleotides, DNA cloning and sequencing, and the study of DNA structure by enzyme and chemical probing and electrophoresis. In addition, immunological and physical methods will be employed.

The laboratory is well funded and this position, which is available immediately, is supported by a grant from the MRC for 3 years. Starting salary £6,600 (under review). Opportunities exist to register for a higher degree.

Informal enquiries may be made to Dr Lilley, (telephone 0382 23181 extension 4243). There is no formal closing date but applications, containing full career details and the names of two referees should be sent as soon as possible to the Personnel Officer, The University, Dundee, DD1 4HN. Please quote reference EST/55/85J. (7084)A

UNIVERSITY OF WALES
COLLEGE OF MEDICINE
DEPARTMENT OF MEDICINE
POST-DOCTORAL
RESEARCH OFFICER

required in the above Department as soon as possible to work in the general field of neuroendocrinology/neurobiology. The areas include the application of radioimmunoassay and HPLC and neurone culture to the study of hypothalamic and other brain neuropeptides. Work also includes the study of the applications of neurotransmitters and neuro-modulators to the control of endocrine function in general and neuroendocrine function in particular. Other methodology involves the measurement of catecholamines by HPLC with electrochemical detection.

Salary on the scale for University Research and Analogous Staff Grade 1A (£7,520-£12,150 per annum, under review); starting point dependent upon qualifications and experience.

Applications, in the form of a curriculum vitae with the names and addresses of two referees (quoting Ref. No. M6/125) should be submitted to the Registrar and Secretary, University of Wales College of Medicine, Heath Park, Cardiff CF4 4XN by July 31, 1985.

Further information available from Dr Maurine Scanlon (Tel No. 0222/755944 ext. 2182). (7086)A

IMPERIAL COLLEGE OF
SCIENCE AND
TECHNOLOGY
DEPARTMENT OF GEOLOGY
RESEARCH ASSISTANT

Applications are invited from persons who wish to join a small research team currently using scanning electron microscopy (JEOL Superprobe) with automated Digiscan image analyser and X-ray energy dispersive spectroscopy, to characterize metal rich particles according to their size, shape and composition. (Microcomputers will be used to improve the resolution of the particle characterization schemes).

In the first instance the object of this research will be to establish a suitable SEM technique for the identification and quantification of lead and other metals in household dust. Several other characterization schemes are being developed, however, and these will be applied to a variety of environmental media.

Applicants (graduates, or equivalent), in a relevant discipline, preferably with a Ph.D., should have experience in operating similar equipment.

This 2 year appointment will be within the RA1A grade £7,520-£12,150 p.a., plus £1,233 London Allowance at a point commensurate with qualifications and experience.

Applicants should send a full C.V. as soon as possible to Dr E. Culbard, Applied Geochemistry Research Group, Department of Geology, Imperial College, Prince Consort Road, London SW7 2BP. Closing date 27 August 1985. Tel. 01-589 5111 ext. 5543. (7110)A

THE UNIVERSITY OF NEW
SOUTH WALES
Sydney, Australia
SCHOOL OF GEOGRAPHY
LECTURER (REF. 1055)

Primary responsibility will be to teach geographic information systems subjects and develop their application in environmental studies in the applied geography programs. Applicants with interests in land evaluation or resource inventory are preferred. A supportive interest in applied remote sensing is desirable.

The position is available from October 1985 and appointment will be on the basis of a contract with provision for conversion to tenure.

Further information from Professor B. J. Garner, Head of School (02) 697-4390, or c/o University of New South Wales, PO Box 1, Kensington, New South Wales, Australia 2033.

Applications close 8 August 1985.

Salary: \$A26,236 range \$A34,467. Commencing salary according to qualifications and experience.

For further information about conditions of appointment and method of application write to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Equality of employment opportunity is University policy. (W2028)A

THE UNIVERSITY OF
WESTERN AUSTRALIA
Perth

LECTURER (TENURED)
(Soil Chemistry)

SCHOOL OF AGRICULTURE (SOIL
SCIENCE AND PLANT NUTRITION)

Applications are invited for appointment as a Lecturer in Soil Chemistry. The appointee would be required to teach in Soil Science units offered in both the Faculties of Agriculture and Science. An ability to teach a wide range of applications of soil chemistry to agriculture is required. The appointee would be expected to develop a research programme in an area of soil chemistry important in agriculture.

Details regarding teaching responsibilities; current research and facilities available can be obtained from Professor A. D. Robson, telephone (09) 380 2505.

Current salary range: Lecturer — \$A26,236-\$A34,467 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme.

Applications in duplicate stating full personal particulars, qualifications and experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009 by 8 August 1985. Conditions of appointment will be specified in any offer of appointment which may be made as a result of this advertisement. (W2023)A

UNIVERSITY COLLEGE
CARDIFF

DEPARTMENT OF BIOCHEMISTRY
TWO RESEARCH
ASSISTANTS

Applications are invited for the above 3 year posts. The research which is supervised by Dr R J Richards, concerns the biochemical and cellular effects of lung toxins and the prevention of alveolar damage. Duties to commence 1st October, 1985 or as soon as possible thereafter.

A) BIOCHEMIST
Grade 1A/1B

Max starting salary £8,920

B) BIOLOGIST/
BIOCHEMIST Grade 1B

Max starting salary £7,980.

The second post will involve spending some time at CDE, Porton Down, and some experience of EM techniques would be an advantage, but is not essential.

Applications, (2 copies), together with the names and addresses of two referees, should be forwarded to the Establishment Officer, University College, PO Box 78, Cardiff CF1 1XL from whom further particulars will be available. Closing date 16th August, 1985. Ref: 2983 A or B as appropriate. (7063)A

THE UNIVERSITY OF
PAPUA NEW GUINEA

Port Moresby

PROFESSOR OF GEOLOGY
P.071001/85

Applications are invited to fill this post which falls vacant at the end of 1985. Applicants should have proven ability of a high calibre in either Economic Geology/Geochemistry/Igneous Petrology or Palaeontology/Stratigraphy/Sedimentology/Marine environment. The successful applicant must be able to liaise productively with individuals and institutions outside the University, as well as providing leadership in teaching and research within the Department of Geology. Preference will be given to applicants with a genuine interest in extending beyond the initial contract period. The appointee will be expected to become administrative Head of Department as soon as possible.

Salary will be K24,355 per annum plus gratuity

Other conditions: The successful applicant will be normally offered a contract for a three year period ending at the end of a semester. The gratuity is based on 24% of salary earned and is payable in instalments or lump sum and is taxed at a flat rate of 2%. In addition to the salary quoted above, the main benefits include: support for approved research; rent-free accommodation, appointment and repatriation airfares for appointee and dependants; financial assistance towards the cost of transporting personal effects to and from Papua New Guinea; 6 weeks annual recreation leave with home airfares available after each 18 months of continuous service, generous education subsidies for children attending schools in PNG and overseas; a salary continuation scheme to cover extended illness or disability. Applicants wishing to arrange secondment from their home institutions will be welcomed. The terms and conditions are under review.

Applications will be treated as strictly confidential and should include a full curriculum vitae, a recent small photograph and the names and addresses of three referees. In order to expedite the appointment procedure, applicants are advised to ask their referees to send confidential reports directly to the University without waiting to be contacted. Applications should be forwarded to the Deputy Registrar (Staffing), University of Papua New Guinea, PO Box 320, University PO, Papua New Guinea, and close on 6 August 1985. Candidates in UK should also send a copy of their application to the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. (W2026)A

FERMENTATION MICROBIOLOGIST

Drug Research

Pfizer is one of the largest and most successful research-based international pharmaceutical companies. In our modern, well-equipped and recently extended laboratories at Sandwich on the Kent coast about 600 scientists and support staff are engaged in the discovery and development of novel compounds for use in human and veterinary medicine.

Our Animal Health group, currently 90 strong, has a major commitment to fermentation as an approach to the discovery of new agents for improving the health and productivity of farm livestock.

We need a creative scientist to contribute to the discovery of novel biologically active agents and to take responsibility for all aspects of our culture maintenance and modification programme.

For this important new position we are seeking a practical Microbiologist with up to three years postdoctoral experience in Actinomycete biology, microbial physiology/biochemistry or genetic techniques who is capable of interacting effectively with other scientists both inside and outside the organisation.

This appointment offers excellent opportunities for personal and career advancement and a highly competitive starting salary together with good bonus, pension and life assurance schemes, generous assistance in relocating to an attractive semi-rural area of coastal Kent, flexible working hours and an active sports and social club with first-class amenities.

Please write in confidence quoting ref N1 giving full details of career to date to Mr D. O'Callaghan, Pfizer Central Research, Ramsgate Road, Sandwich, Kent CT13 9NJ. (7100)A

Pfizer

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

ACADEMIC DEPARTMENT OF
HAEMATOLOGY

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant with the Bone Marrow Transplantation Team. Applicants should have MSc or equivalent, with undergraduate training in biosciences and postgraduate training in human pathology particularly haematology. Work experience in clinical and laboratory haematology desirable.

The successful candidate will be responsible for collection, collation and analysis of data for clinical studies; preparation of reports, abstracts and papers, and for investigation of new developments or problems.

Salary on scale £6,000-£8,920 (under review) + £1,233 London Allowance according to qualifications and experience.

Further details available from the School Office, R.F.H.S.M., Rowland Hill Street, London NW3 2PF (01-794 0500 ext. 4262) to which applications (full curriculum vitae and names and addresses of two referees) should be sent by 26 July 1985. Please quote reference AVH/RA. (7099)A

UNIVERSITY OF GUELPH

DEPARTMENT OF ANIMAL AND POULTRY SCIENCE

The Department of Animal and Poultry Science, University of Guelph, seeks faculty members at the assistant/associate rank for tenure-track positions in molecular genetics or biochemical genetics.

The successful applicants will be expected to develop strong research programs in gene transfer and the expression of genes in developing avian and/or mammalian embryos. Major emphasis will include mediation of gene transfer by retroviral transduction, recombinant DNA techniques, gene cloning, splicing and transfer. The appointees will be expected to be an integral part of a university team approach to genetic engineering of farm animals.

In addition to establishing a vigorous laboratory, the incumbents will also be expected to participate in the ongoing undergraduate and graduate teaching programs of the department.

A Ph.D. degree with demonstrated expertise in molecular genetics or a related field is required. Applicants should submit curriculum vitae, bibliography, recent reprints, transcripts, and three letters of reference to:

**Dr. G. K. Macleod, Acting Chairman
Department of Animal & Poultry Science
University of Guelph
Guelph, Ontario, Canada N1G 2W1**

Closing date for receipt of applications is August 30, 1985 or until the positions are filled.

Citizenship is not a factor for consideration.

Subject to final budgetary approval.

(NW29)A

SANDOZ LTD.
Biopharmaceutics Department

NATURAL SCIENTIST OR PHARMACEUTICAL TECHNOLOGIST

required to work on pharmacokinetic aspects of new drug development.

In conjunction with medical, bioanalytical and drug-formulation specialists, your brief will be to plan studies in clinical and preclinical phases and to evaluate the results using both pharmacokinetic/pharmacodynamic and statistical models. Methodological innovation will be encouraged.

Applicants should have a good grasp of the fundamentals of pharmacokinetics and an understanding of biological problems, plus a knowledge of EDP and statistics. Post-doctoral research or industrial experience would be an advantage. A knowledge of German is also desirable.

Candidates with appropriate qualifications are invited to submit their written applications to:

SANDOZ

SANDOZ LTD.
Personnel Department, Ref. 8554
CH-4002 Basle
Switzerland

(W2018)A

DEPUTY DIRECTOR, GENERAL SCIENCES Salary Open

Duties: Reporting to the Laboratory Director, the Deputy Director of General Sciences provides overall direction for Laboratory divisions in high energy physics, nuclear physics, accelerator physics, and fusion research. Major responsibilities include management oversight of these divisions, coordination of inter-divisional programs and activities, establishment and implementation of goals consistent with the Laboratory's mission, interaction with policy and advisory committees to ensure the highest quality of scientific achievement, and management liaison with the University of California, the U.S. Department of Energy, and other external agencies.

Requirements: A distinguished record of scientific achievement and proven leadership in managing interdisciplinary programs in fields such as high energy physics, nuclear physics, accelerator physics, or fusion research. Proven success in interacting with academic institutions, scientific laboratories, private industry, and the federal government (especially the U.S. Department of Energy). Must have a Ph.D. in the physical sciences or equivalent experience. Requires strong management skills in areas of decision-making, problem-solving, interpersonal communications, staffing, funding, and facilities planning and utilisation. "Position is subject to the financial disclosure requirements of the California Political Reform Act of 1974."

Please submit two copies of resumé including salary history and names and addresses of references to:

Chairman, Search Committee
Lawrence Berkely Laboratory
Employment Office
1 Cyclotron Road
Building 90, Room 1012
Berkeley CA 94720

Refer to Job#B/3425. Resumés must be received in the Employment Office by September 1, 1985, 5.00 p.m. *An Equal Opportunity Employer M/F/H.* (NW14)A

MASSEY UNIVERSITY
Palmerston North, New Zealand
DEPARTMENT OF BOTANY
& ZOOLOGY

LECTURESIPS

Applications are invited for two lectureships in the above Department. Consideration will be given to suitably qualified applicants, but preference may be given to those with research experience and/or special interests in:

BOTANY

- (i) Plant cell biology
- (ii) Population biology
- (iii) Plant genetics
- and/or Plant biosystematics

ZOOLOGY

- (i) Population biology
- (ii) Invertebrate zoology (except Insects)
- (iii) Aquatic zoology
- (iv) Development biology

The appointees will be expected to teach internal and extramural students at the undergraduate level, contribute to postgraduate teaching, and establish and develop research in their own field of interest.

Salary on the Lecturer's scale: NZ\$23,622-\$27,928.

Conditions of appointment are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or from the Registrar of the University, with whom applications close 30 August 1985. (W2025)A

WHO COLLABORATING CENTRE CHELSEA HOSPITAL FOR WOMEN RESEARCH ASSISTANT

Applications are invited for the above post to work on the development of an immunoassay for gossypol, a potential male antifertility agent.

Applicants (post doctoral or equivalent experience) should have experience in the development of immunoassays for low molecular weight analysis. Some knowledge of chemical syntheses would be advantageous.

The post is available immediately for a period of one year with the possibility of extension. Salary in the 1A Range for Research and analogous staff (£7,520-£9,390 plus London Weighting).

Applications (curriculum vitae plus the names of 2 referees) should be sent by 24 July to: WHO Collaborating Centre for Immunoassay, Chelsea Hospital for Women, Dovehouse Street, London SW3 6LT.

Informal enquiries may be made to: Mr S Sufi or Dr A Donaldson (telephone 01-351 9336). (7091)A

**UNIVERSITY OF
LEICESTER**
DEPARTMENT OF PHYSICS
RESEARCH ASSOCIATE

Applications are invited for a SERC-funded research associateship for work on the theory of reflection high energy electron diffraction (RHEED). This is a rapidly developing area of surface science with important applications in semiconductor growth. The successful applicant will be expected to develop the theory and computer programs used for RHEED intensity analysis. This will involve close contact with experimental groups working in industrial and academic research. Candidates should have a Ph.D. or expect to obtain one shortly. Experience of either computational solid state physics or of interpreting experimental data would be an advantage. The post is tenable for up to 3 years from 1st October or as soon as possible thereafter, and the initial salary will be £7,520 or £7,980 per annum (under review) depending on age and experience. Applications, including a CV and the names of two referees, should be sent to Dr P A. Maksym, Department of Physics, University of Leicester, Leicester LE1 7RH, as soon as possible. (7096)A

UNIVERSITY OF GLASGOW
DEPARTMENT OF
PATHOLOGY
WESTERN INFIRMARY

A Ph.D. graduate with 3 years' post-doctoral research experience in protein chemistry is required for a three year Arthritis and Rheumatism Council project grant in the University of Glasgow. The aim of the project is to isolate and characterize a plasma protein which interferes with the complement-mediated solubilisation of antigen-antibody complexes. Salary, on the University Scale 1A. Applications with C.V. and names and addresses of two referees to Professor K. Whales, Department of Pathology, Western Infirmary, Glasgow G11 6NT by 25th July, 1985. (7097)A

**UNIVERSITY OF
CAMBRIDGE**
DEPARTMENT OF
HAEMATOLOGICAL MEDICINE
RESEARCH ASSOCIATE

Applications are invited from post-doctoral or otherwise experienced graduates to participate in a research programme involving the cytogenetic analysis of abnormal clones and detailed determination of breakpoints in structural rearrangements in myeloma and their relation to oncogene activation and paraprotein production.

Salary on an age-related scale, e.g. £7,980 at age 25 to £10,330 at age 30. Applications with c.v. and names of two referees to Professor F. G. J. Hayhoe, Department of Haematological Medicine, Hills Road, Cambridge CB2 2QL before 31 July, 1985. (7104)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH FELLOW

Applications are invited, as soon as possible, for the above post for the study of haem metabolism in plants and its significance in the synthesis and organisation of photosynthetic pigments. The successful applicant will join a group studying various aspects of tetrapyrrole biochemistry and their application to medical and biological problems.

The post is funded by the SERC and is available for a fixed period of up to three years from a starting date to be agreed. Applicants should hold, or expect to hold shortly, a PhD in a relevant discipline.

Informal enquiries may be made to Dr S B Brown (Tel 0532 431751 ext 7500).

Salary on the IA Range of Research and Analogous Staff (£7,520 — £12,150) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT quoting reference no 83/64. Closing date for applications 31 July 1985. (7073)A

ENZYMOLOGIST

Applications are invited from persons with experience in the semi-commercial production of enzymes (pilot plant scale).

Successful applicant would be expected to organise team for new projects. Write giving full details of past experience: Maybridge Chemical Co Ltd Tintagel, N Cornwall PL34 0HW. (7076)A

UNIVERSITY OF OXFORD Research Laboratory for Archaeology

POST-DOCTORAL POSITION IN CHEMISTRY

A post is available, tenable for 3 years from October 1985 for a post-doctoral chemist to develop methods in radiocarbon dating

A 2MV Accelerator Mass Spectrometer is used for routine and research dating of milligram-sized organic samples. Improved methods of sample analysis, purification and ion source target preparation, and better understanding of the effects of burial environments are sought.

Applicants should have some research experience, preferably in organic chemistry. Salary will be on Scale 1A, Points 1-5 (£7,520 — £9,390) depending on age and experience. Applications should be made to Dr R E M Hedges, Director, Radiocarbon Accelerator Unit, Research Laboratory for Archaeology, 6 Keble Road, Oxford OX1 3QJ, and should include details of qualifications and experience and the names of two referees. (7059)A

THE UNIVERSITY OF WESTERN AUSTRALIA Perth

LECTURER (LIMITED TENURE) (Soil Microbiology)

SCHOOL OF AGRICULTURE (SOIL SCIENCE AND PLANT NUTRITION)

Applications are invited for appointment as a Lecturer in Soil Microbiology for a term of three years. The appointee would be required to teach in both Soil Science and Agricultural Microbiology units in the Faculties of Agriculture and Science. An ability to teach a wide range of applications of soil microbiology to agriculture is required. Research interests in any of the areas of rhizobial ecology, mycorrhizal symbioses, or microbial involvement in chemical transformations in soils would be desirable but not essential.

Details regarding teaching responsibilities, current research and facilities available can be obtained from Professor A. D. Robson, telephone (09) 380 2505.

Current salary range: Lecturer — \$A26,236-\$A34,467 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family, and removal allowance.

Applications in duplicate stating full personal particulars, qualifications and experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009 by 8 August 1985. Conditions of appointment will be specified in any offer of appointment which may be made as a result of this advertisement. (W2024)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF PATHOLOGY RESEARCH FELLOW/ ASSISTANT IN TUMOUR IMMUNOLOGY

Support is available for 1 year from 1 October 1985 for a suitable individual to work on the characterization of anti-inflammatory factors generated during tumour growth. The post, which is funded by the Cancer Research Campaign, is suitable for applicants who have or are about to obtain a Ph.D. in biochemistry, immunology or cell biology, or to candidates with a good first degree in either of these subjects. Some experience in protein fractionation/characterization would be an advantage but is not essential.

Salary within range £7,520-£9,860 per annum on the Range 1A Scale for Research and Analogous Staff with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 2 August 1985. (Ref EA/008). (7094)A

BIOGEN

is an international biotechnology company with laboratories in Switzerland, Belgium and the United States in the development of new pharmaceutical products through genetic engineering.

Vacancies now exist in our Geneva facility for well qualified scientists who are skilled in the areas of:

Cell Biology
Protein Chemistry
Fermentation Technology
Immunology

Post doctoral positions are also available in these areas.

We offer a challenging scientific career with the opportunity to interact with talented colleagues in a stimulating environment.

If this offer appeals to you, then reply to:

Rita Gloor, Personnel Manager
BIOGEN S.A.
route des Acacias 46
1227 Geneva
Switzerland

Please send your resumé and a list of three individuals who may be contacted for references on your behalf. All replies will be evaluated in confidence. (W2015)A

National Research
Council Canada

Conseil national
de recherches Canada

Yeast Geneticists Montréal, Québec

Positions are available, at the post-doctoral level, in a group studying the molecular genetics of the yeast *Saccharomyces cerevisiae*. Qualified candidates with experience or an interest in gene expression and protein secretion are invited to apply.

The group is working within the new Biotechnology Research Institute located close to McGill University in Montréal and has several collaborations with universities, industry and other research institutes. The Institute has several groups working on molecular genetics and is superbly equipped.

Benefits are fully competitive and salary will be commensurate with qualifications and experience.

Please send a detailed curriculum vitae with 3 references to: The Manager, Employment Office, National Research Council of Canada, Ottawa, Ontario, K1A 0R6. In reply please quote RB-84-25. (NW40)A

Canada

THE UNIVERSITY OF CALGARY ASSISTANT PROFESSOR IN MOLECULAR BOTANY

The University of Calgary, Department of Biology, invites applications for a tenure-track position in Molecular Botany at the assistant professor level. While the successful candidate should be able to complement and co-operate with existing research programs in plant and cell biology and plant physiology, the main goal is to develop a strong independent research program in the molecular biology of plants. Current areas of interest in the Department are plant growth and development, and the molecular basis of the response of plants to stress, but the candidate is not restricted to these. Experience with the techniques of recombinant DNA and related technologies is essential.

Teaching duties will include lecturing in an introductory general botany course and in senior courses concerned with the biochemical/molecular aspects of higher plants.

A well equipped research laboratory is available. Other equipment is also available in plant physiological and molecular biological laboratories within the Department.

The appointment will be open as of December 1, 1985, with a starting salary in the range of \$29,741 — \$34,489 (currently under review).

All qualified individuals are encouraged to apply but preference will be given to Canadian citizens and permanent residents.

Applicants are requested to submit a complete curriculum vitae, and to have three letters of academic reference forwarded by September 30, 1985 to: Dr. R.W. Davies, Head, Department of Biology, The University of Calgary, 2500 University Drive N.W., Calgary, Alberta, Canada T2N 1N4 (NW13)A

UNIVERSITY OF BATH SCHOOL OF CHEMISTRY

RESEARCH OFFICER IN MOLECULAR GRAPHICS

This is a 3 year position, as a member of a newly-established interdisciplinary unit within the science area, located in the School of Chemistry. The successful candidate will undertake research in any appropriate area within chemistry and will also assist, on a fully collaborative basis, researchers from other schools, including pharmacy and pharmacology, and biochemistry.

The unit will be equipped with an Evans and Sutherland PS330 micro VAX II. Access to mainframe computers is available. Links to a network of computers are planned.

Applicants should have an appropriate background in molecular graphics or in a relevant area.

Salary in the range £7,520–£12,150 p.a. according to qualifications and experience.

Informal contact may be made with Professor M. M. Campbell, School of Chemistry (0225 61244 ext. 565).

Further particulars and application forms from the Personnel Officer, University of Bath BA2 7AY, quoting Ref. No. 85/108. Closing date: 30-7-85. (7108)A

RESEARCH FELLOW

1 year term appointment,
subject to renewal

Accession and catalog a fossil fish collection from Brazil. Also write factual text for illustrated atlas and catalog, and conduct systematic research on species in the collection.

The ideal candidate will have the following credentials: 1) PHD in the natural sciences area desired; 2) A background in ichthyology or paleoichthyology; 3) Previous publications experience. A knowledge of bony fishes also is desired.

The starting salary is \$17,000 per annum with excellent benefits. To apply, send résumé along with references to: Jerome Williams, Personnel Department.

BIOCHEMISTRY**

**POST-DOCTORAL
RESEARCH ASSISTANT**

Applications are invited for the position of Post-Doctoral Research Assistant, funded by the CRC for 3 years from 1 October 1985, to study the expression of cellular genes which respond to the infection of human B-lymphocytes with Epstein-Barr Virus. The post will be in a well-equipped medical molecular biology unit within the School. Experience with recombinant DNA techniques would be advantageous, but not essential. Salary within the range £8,753-£10,153. Applications, including CV and names of 2 referees, to Dr P. M. Brickell at the above address. (7111)A

BIOCHEMIST/CHEMIST

G.D. Searle is a major international pharmaceutical company whose Research & Development Division at High Wycombe is involved with the discovery of new chemical and biological entities.

A vacancy has arisen within our PROTEIN ENGINEERING DEPARTMENT for a graduate scientist to join an established team involved in the design and production of modified proteins using recombinant DNA techniques. Experience of oligonucleotide synthesis or the enzymatic manipulation of DNA would be an advantage.

The Company offers competitive salaries, 23 days holiday, contributory pension fund, health insurance scheme, subsidised cafeteria, recreation club and modern offices in a very pleasant location. Generous relocation assistance will be available in appropriate cases.

Please apply to the Personnel Manager, Searle Research & Development, Lane End Road, Sands, High Wycombe, Bucks. (Tel. High Wycombe 21124, Ext. 3372). Please quote reference R30/136.

SEARLE

UNIVERSITY OF ULM

MOLECULAR BIOLOGIST or PROTEIN CHEMIST

Applications are invited for PRE- OR POST-DOCTORAL RESEARCH FELLOWSHIPS funded for three years commencing January 1st, 1986 (Salary according to BAT II a/b). A research group will focus on the expression of oncogenes during regulation and dysregulation of cell growth and cell transformation by the DNA-tumor virus SV40. Applicants should have experience in DNA technology and analysis of gene expression or alternatively in protein chemistry.

Applications including CV and the names of two referees should be sent to Prof. R. Henning, Department of Biochemistry, University of Ulm, P.O. Box 4066, D-7900 Ulm, West Germany.

(W2013)A

DIRECTOR

BERMUDA BIOLOGICAL STATION

Applications are invited for the position of Director of the Bermuda Biological Station for Research Inc.

The Director is the chief executive officer of the Station, with responsibility for all day-to-day operations, planning, and overall enhancement of scientific programs. The Director should have a Ph.D. in marine science and experience in administration and research funding. Responsibilities include financial management, development and public relations, recruiting and evaluation of senior staff, and maintenance of facilities. Salary is negotiable.

The Station is an independent U.S. not-for-profit marine laboratory with facilities for resident and visiting scientists and students. There are research and teaching laboratories, a small research fleet, workshops, an excellent library, a staff of 35 and accommodations for up to 140.

Send applications to W. R. Wright, BBS President, Box 54, Woods Hole, MA 02543, U.S.A. (NW30)A

ANGLIAN BIOTECHNOLOGY LTD

We are a progressive research and development company specializing in recombinant DNA technology for research, and diagnostic purposes.

We are based in Colchester, a town with fast and frequent connections to London, and have modern air conditioned facilities. We have large scale fermentation and production units as well as an active R & D programme.

We require:

- Microbiologist/ Fermentation specialist** for responsibility in cell culture and down stream processing.
- Postdoctorate and/or graduate Molecular Biologists.**

Please apply in writing with full CV to:

UNIVERSITY OF MANITOBA Department of Human Genetics

MOLECULAR GENETICIST

The Department of Human Genetics, Faculty of Medicine, University of Manitoba, invited applications for a full-time Assistant Professor to commence as soon as possible and certainly by January 1, 1986. Applicants should have demonstrated research experience in Molecular Genetics, particularly in the areas of genome organization, control of gene expression or gene mapping. A Ph.D., post-doctoral training and potential for an independent career as an experimental scientist are prerequisites.

The university encourages both women and men to apply for positions. In accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents.

A concise description of projected research goals and interests, the names of at least three referees, and a curriculum vitae should be sent to Dr John L. Hamerton, Department of Human Genetics, Faculty of Medicine, University of Manitoba, 250-770 Bannatyne Avenue, Winnipeg, Manitoba, Canada R3E 0W3. (NW22)A

THE POLYTECHNIC WOLVERHAMPTON

LECTURER II IN CHEMISTRY AND COMPUTING (temporary)

The post involves lecturing in organic and/or physical chemistry. The successful applicant will be expected to participate in team research in involving computer-controlled automated solid phase peptide synthesis

RESEARCHER A IN ORGANIC CHEMISTRY (temporary)

This post involves in ultra-high solid (gel) phase peptide synthesis. The successful applicant will be expected to register for a CNA A MPhil or PhD degree

RESEARCH ASSISTANTS (2 posts — 3 years) RESEARCHER A

Metals in gastrointestinal physiology and pharmacology and metabolism of intestinal peroxisomes. Previous research experience an advantage for one post in inorganic pharmacology. For the other post, experience of subcellular fractionation and NMR preferred but not essential. Registration for MPhil/PhD (CNA A) is expected

POST-DOCTORAL RESEARCH FELLOW (1 post - 2 years) RESEARCHER B

Required for study on metal-ion interactions in intestinal absorption. Experience in gastrointestinal physiology/pharmacology essential. Familiarity with AAS, XRF, NMR, TEM, and SEM techniques an advantage. Interdisciplinary approach essential.

Informal enquiries to Dr N J Birch. Salary Scales: Lecturer II — £7,548 — £12,099; Researcher A — £5,910 — £6,657; Post-doctoral Research Fellow — £7,548 — £10,251.

Further details and application forms from The Staffing Office, The Polytechnic, Wolverhampton WV1 1SB or telephone Wolverhampton (0902) 710654 (ansaphone) (7080)A

UNIVERSITY COLLEGE
CARDIFFDEPARTMENT OF METALLURGY
AND MATERIALS SCIENCE
LECTURER

Applications are invited for the above post. Preference will be given for someone prepared to research into non-metallic materials. The appointment will be made at the lower end of Lecturer's scale £7,520 — £14,925 per annum. Duties to commence as soon as possible.

Applications (3 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) & Registrar, University College, PO Box 78, Cardiff CF1 1XL from whom further particulars are available. Closing date 9th August, 1985. Ref: 2985. (7060)A

UNIVERSITY OF DURHAM

Plant Molecular Biology Group, to work on the molecular basis for control of seed protein gene expression in pea. This work will form part of a continuing programme on proteins in legume seeds and their encoding genes, and will involve gene transfer techniques in plants. Experience in working with plant nucleic acids of *Agrobacterium* gene transfer systems would be an advantage, but is not essential.

The post funded by the SERC and tenable for three years from October 1st 1985, or as soon as possible thereafter.

Initial salary £7,520 — £8,920 (under review) on Range 1A with superannuation.

Applications (3 copies) naming three referees to be returned by 26 July 1985 to the Registrar, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained.

POST-DOCTORAL RESEARCH ASSISTANT IN ASTRONOMY

DEPARTMENT OF ASTROPHYSICS

OXFORD UNIVERSITY

It is expected that an SERC-supported post will be available from October 1985 for a Post-Doctoral Research Assistant in the Astrophysics Department to work on the observation and interpretation of cataclysmic variables and related objects. The post is tenable for up to 3 years at a starting salary of up to £8,450 (age point 26), which is currently under review.

Applicants should send a resumé and themselves request 2 referees to write to: Dr. P.A. Charles, Department of Astrophysics, University of Oxford, South Parks Road, Oxford OX1 3RQ, UK.

Deadline for receiving applications is August 30, 1985. (7081)A

UNIVERSITY OF EAST ANGLIA

Norwich

POST-DOCTORAL POST IN PLANT SCIENCE

A 3 year position funded by the AFRC is available to work on biochemical aspects of the effects of anoxia on plants. Candidates should have a PhD in biochemistry/physiology. The project involves collaboration between the University of East Anglia and the John Innes Institute.

Enquiries and applications, including full CV and the names of three referees should be addressed to Professor D D Davies, School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ. Applications should be received within 2 weeks of the publication of this notice. (7068)A

UNIVERSITY OF LEICESTER

DEPARTMENTS OF BIOCHEMISTRY AND CHEMISTRY

2 POSTDOCTORAL RESEARCH ASSOCIATES MOLECULAR BIOLOGIST AND BIOLOGICAL CHEMIST TO INVESTIGATE MECHANISMS OF RNA PROCESSING

Applications are invited for these two SERC-funded posts to carry out research on eukaryotic RNA processing mechanisms using nucleotide analogues, in collaboration with Drs I. C. Eperon (Biochemistry) and B. V. L. Potter (Chemistry).

Candidates should possess a Ph.D. and experience or interest in molecular biology or nucleic acid chemistry (training in molecular biological techniques will be provided).

The posts will be tenable for three years, and salary will be within the range £7,520-£12,150 p.a., depending on qualifications and experience. Applications (including a c.v. and names of two referees) should be sent to either of the above at University of Leicester, Leicester LE1 7RH, U.K., to arrive not later than 16 August (7105)A.

NOTTINGHAM UNIVERSITY

DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral position to carry out protein engineering of an E.coli vitamin B12-requiring enzyme. The work will involve the use of genetic and biochemical methods of gene manipulation (including site-specific mutagenesis) to define amino acid residues involved in vitamin B12 binding and enzyme function.

This grade 1A SERC-supported position, tenable for three years, has a starting salary of £7,520 (under review) including USS benefits.

Applicants with suitable experience in recombinant DNA technology should send a curriculum vitae and the names of two referees to Dr Robert E Glass, Department of Biochemistry, Medical School, Queen's Medical Centre, Nottingham NG7 2UH (telephone: 0602-70011 Ext 3395) from whom further information may be obtained.

(7069)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF GEOLOGY LECTURESHIP IN SEDIMENTOLOGY

Applications are invited for the above post. It involves broad teaching duties in the context of Geology degree schemes, but carries special responsibility for undergraduate and graduate courses in sedimentology. The successful candidate will be expected to develop departmental facilities and research activities in sedimentology. Preference will be given to applicants who have a strong research interest in clastic sedimentology. Salary range £7,520 — £14,925 per annum. Duties to commence 1st October, 1985 or as soon as possible thereafter.

Applications (two copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL. From whom further particulars will be available. Closing date 8th August, 1985. Ref 2980. (7064)A

Faculty Position available, tenure-track, in molecular genetics, with a special interest in membranes. Applicants should have research background in recombinant DNA technology (preferably also in somatic cell genetics) and working knowledge of membrane proteins. M.D. and/or Ph.D. in appropriate field required. Successful candidate will hold tenure-track appointment (Assistant or Associate Professor, depending upon qualifications) in Department of Physiology and Molecular Biophysics at Baylor College of Medicine. Joint appointments in relevant academic departments also possible. Laboratory space and basic equipment provided and initial laboratory support available. Successful candidate will devote majority of his/her effort to establishing and maintaining an independent research program related to the main interests of the Department. The Department is building a strong program in membrane biophysics with expertise in electrophysiology, membrane biochemistry, reconstitution, and modelling. **Send vita, a brief description of past and present research experience, and names of three or more references to**

Dr. A. M. Brown, Incoming Chairman, Physiology and Molecular Biophysics Department

**Baylor College of Medicine,

SEMINARS & SYMPOSIA

HUMAN GENETICS 1985

A Symposium organized by the Committee on Genetic Experimentation (COGENE) of the International Council of Scientific Unions (ICSU) and co-sponsored by the Institut National de la Santé et de la Recherche Médicale (INSERM) and the Association pour la Recherche contre le Cancer (ARC), will take place in Paris between October 2-4, 1985. The Program of the Symposium has been arranged by an Organizing Committee formed by G. Bernardi, F. Gros (co-chairmen), S. N. Cohen, W. Mommaerts, R. Monier, A. Skalka and R. Williamson. The five sessions of the Symposium will deal with:

- (1) The human genome
- (2) Oncogenes and cancer
- (3) Gene control and development
- (4) Genetic diseases
- (5) Perspectives in diagnosis and gene therapy

Session chairmen and speakers comprise: W. Arber (Basle), M. Bassendine (Edinburgh), G. Bernardi (Paris), M. Buckingham (Paris), A. de la Chapelle (Helsinki), D. Cohen (Paris), C. Croce (Philadelphia), J. Dausset (Paris), C. de Duve (Bruxelles), L. Ernster (Stockholm), G. Felsenfeld (Bethesda), F. Gros (Paris), F. Jacob (Paris), U. Littauer (Rehovot), L. Luzzatto (London), J.-L. Mandel (Strasbourg), J. O'D. McGhee (Oxford), W. Mommaerts (UCLA), R. Perry (Philadelphia), U. Pettersson (Uppsala), E. de Robertis (Basle), J. Rosa (Créteil), D. Stehelin (Lille), J. G. Sutcliffe (La Jolla), D. Weatherall (Oxford) and R. Williamson (London).

Attendance at the Meeting will be free of charge; a pre-registration is required and can be obtained by writing to Dr G. Bernardi, Laboratoire de Génétique Moléculaire, Institut Jacques Monod, 2 Place Jussieu, 75005 Paris (France).

THE UNIVERSITY OF LEEDS MSc in CARDIOVASCULAR STUDIES

A one year full-time course which provides a training for scientific investigations into the human and other mammalian cardiovascular systems

The course consists of lectures, tutorials and laboratory work which provide experience in. Isolated tissue studies; Mammalian systems physiology; Cardiovascular investigation in man; Exercise physiology, Pathophysiology of the cardiovascular system, Neuronal control of the circulation, Respiratory physiology; Advanced studies in cardiology

A major component of the course is a three month research project.

The course is open to graduates in medicine, physiology and related disciplines and commences 1 October each year. For further details write as soon as possible to the Department of Cardiovascular Studies, The University, Leeds LS2 9JT. (7072)C

ASSISTANTSHIPS

CAMBRIDGESHIRE COLLEGE OF ARTS AND TECHNOLOGY

(Equal Opportunity Employer)

DEPARTMENT OF SCIENCE
RESEARCH
ASSISTANTSHIPS (LEA)

Research Assistants (3) are required from 1st September, or as soon as possible thereafter, to carry out supervised research in the following areas:

1. Radionuclide and rare earth element geochemistry
2. Plant genetic engineering
3. Mammalian semiochemistry
4. Insect-plant biochemical interactions (use of micro-electrochemical sensors)

Applicants should possess a good honours degree, or MSc, in any appropriate discipline, and will be expected to register for the MPhil/PhD degree of the CNA. They may be required to carry out a limited amount of teaching. The posts are for three years in the first instance, with the possibility of extension for up to one year.

Please state the post(s) for which application is made

Salary Scale: £5,181 — £5,910 (award pending) Candidates with a higher degree start at £5,424.

Details and forms, to be returned by 26th July, from Administrative Assistant, Department of Science, CCAT, East Road, Cambridge CB1 1PT, Tel: (0223) 352992. (7058)P

FELLOWSHIPS

THE AUSTRALIAN NATIONAL UNIVERSITY

Faculty of Science

DEPARTMENT OF BOTANY

VISITING FELLOWSHIPS

Applications are invited for Visiting Fellowships in the Department of Botany, Faculty of Science, to be taken up during the next two years. These awards are intended to assist scientists working in any field of plant science, including genetics and microbiology, to spend a period of between 3 and 12 months carrying out research and/or preparing material for publication. The work may, but need not, involve collaboration with a member of the Botany Department. Visiting Fellows are expected to work in the Botany Department for most of the period of their appointment, during which time office/laboratory accommodation and adequate facilities for a agreed programme will be available. University housing at prevailing rates may also be provided.

Two types of Visiting Fellowship are offered: (1) Alexander von Humboldt — Australian National University Visiting Fellowships, for applicants based outside Australia and New Zealand, of value \$A4,000; (2) Visiting Fellowships for applicants based in Australia or New Zealand, of value \$A1,000. The grant are intended to assist towards travel costs and other expenses.

Applicants, who must have demonstrated research ability, should provide a curriculum vitae and list of publications together with an informative account of their proposed work as a Visiting Fellow and a statement on the proposed timing of the visit; applications quoting Ref FS 20.6.1, should reach the Acting Registrar of the University, GPC Box 4, Canberra, ACT 2601, Australia, by 30 September 1985. Further information on these Fellowships and on Botany Department facilities, staff, courses and research interests can be obtained from Professor J. Warren-Wilson, Head of the Department of Botany, Australian National University (062) 492866.

Further particulars also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square London WC1H 0PF. The University is an equal opportunity employer. (W2027)E

POSTDOCTORAL FELLOWSHIP IN MOLECULAR NEUROBIOLOGY

Friedrich Miescher-Institut,
Basel, Switzerland.

Applications are invited for an internally funded fellowship, of three years maximum duration, to join an established team working on the expression of neuron-specific proteins in developing brain using recombinant DNA techniques. A good training and demonstrated ability in molecular biology are essential. The Institute provides outstanding facilities in a purely research environment. Inquiries should be addressed to Dr A. Matus, Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 Basel, Switzerland. (W2014)E

continued on page 19

UNIVERSITY OF WARWICK

POST-DOCTORAL
RESEARCH FELLOWSHIP
BIOLOGICAL SCIENCES

Applications are invited for an SRC-funded post-doctoral research fellowship to investigate the molecular mechanism of extracellular enzyme export in *Erwinia trovora*. The project will involve enzyme (pectinases, cellulases and proteases) localization techniques, mutant analysis, gene cloning, sequencing and gene product identification. Applicants should have, or shortly expect to have, a PhD, and candidates with skills in molecular biology and/or enzymology will be referred.

The position is for 3 years and is available from 1st October, 1985. Salary on the 1A scale: £7,520 to £12,150 pa. Applicants should send a CV (including a full list of publications) with the names and addresses of two referees, to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, quoting reference GPCS/NAR. Additional information can be obtained from Dr G P Almond on ext 6098.

Closing date: 26th July, 1985
(7085)E

POSTDOCTORAL RESEARCH FELLOWSHIPS

The LBI-Basic Research Program emphasizes research on eukaryotic gene expression and regulation, molecular oncology, prokaryote and eukaryote genetics, protein chemistry, and chemical carcinogenesis. The senior staff members and their research interests are as follows:

George F. Vande Woude: molecular basis of neoplastic transformation

Mariano Barbacid: oncogenes in human and carcinogen-induced animal tumors

Stephen Hughes: retroviral vectors, expression of cytoskeletal genes

James N. Ihle: regulation of hematopoietic/lymphoid differentiation, molecular mechanisms of leukemogenesis

George N. Pavlakis: eukaryotic gene regulation, molecular mechanisms of cell transformation

Stephen Oroszlan: immunochemistry and protein chemistry of retroviruses, structure and function of retroviral gene products

Alan Rein: retroviral genetics, functional analysis of retroviral genes using natural and synthetic mutants

Nancy Rice: genomic organization of endogenous and exogenous retroviruses, transforming genes, cloning, DNA sequencing, expression

Maurice Cohen: molecular biology of human retroviruses, developmental regulation of expression

William Lijinsky: environmental carcinogenesis, mechanisms of carcinogenesis by nitrosamines and related compounds

Anthony Dipple: carcinogen-DNA interactions, aromatic polycyclic hydrocarbon metabolism

Christopher Michejda: organic chemistry and biochemistry of carcinogen activation

Jeffrey Strathern: cell type regulation, genome rearrangement in yeast

Stuart Austin: regulation of replication, segregation of and gene expression by autonomous replicons

Neal Copeland: molecular genetics of murine leukemogenesis, developmental genetics, transposable elements and retroviruses

Nancy Jenkins: insertional mutagenesis by retroviral DNAs, transgenic mice, molecular biology of mouse development

For further information, contact Dr. Maurice L. Guss, LBI-Basic Research Program, NCI-Frederick Cancer Research Facility, P.O. Box B, Frederick, Maryland 21701-1013

(NW28)E

THE ANIMAL VIRUS RESEARCH INSTITUTE
POST-DOCTORAL FELLOWSHIP IN
MOLECULAR BIOLOGY

(Funded by The Overseas Development Administration)

Applications are invited for a 4 year fellowship (beginning October 1st 1985) to work on analysis of the genome of capripox viruses and their development for use as a eukaryotic vector system.

The successful candidate will work with Dr Donald Black in The Division of Molecular Biology. He/she should have a degree in Biochemistry or a related subject and a PhD. Experience with expression systems and eukaryotic gene analysis would be an advantage.

The salary will be in the scale £7,788 to £10,541 (Higher Scientific Officer Grade). Sick leave and non-contributory superannuation schemes, 22 days annual leave. Accommodation may be available. The AVRI is an equal opportunity employer.

Application to include a curriculum vitae and the names of two referees should be sent as soon as possible to the Secretary, Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey GU24 0NF. Tel. 0483 232441. (7010)E

IMMUNOLOGY

POST-DOCTORAL FELLOWSHIP

The Veterinary Infectious Disease Organization (VIDO), a dynamic and growing research institute located at the University of Saskatchewan is seeking applications for a post-doctoral position. The successful applicant will join a group investigating the biology and immunological properties of bovine recombinant recombinant α and γ interferon. Although the applicant will be primarily involved with *in vitro* studies, there will be ample opportunity to participate in *in vivo* trials as well. The virus models being investigated are enteric (rotavirus and coronavirus) and respiratory (bovine herpesvirus-1) infections in cattle.

Expertise in modern cellular immunological techniques and a PhD in immunology is required.

Salary range \$22,000 — \$25,000. Salary commensurate with experience. Send résumé and telephone numbers of three referees to:

Dr Lorne A Babiuk
Associate Director (Research)
Veterinary Infectious Disease Organization
124 Veterinary Road
Saskatoon, Saskatchewan
S7N 0W0.

(NW21)C

E M B O

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION
SHORT TERM FELLOWSHIPS
in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 102240, F.R.G. (W1577)E

ASSISTANTSHIPS CONTINUED

TEESSIDE POLYTECHNIC

Department of Chemistry

LEA RESEARCH ASSISTANTSHIP
IN SYNTHETIC ORGANIC CHEMISTRY

Applications are invited from suitable qualified candidates for an LEA Research Assistantship in Organic Chemistry.

The programme, leading to the degrees of MPhil and/or PhD is concerned with the synthesis and biological evaluation of potential anti-tumour agents, to commence in September 1985 for 3 years only. Candidates will be expected to have or expect to obtain a first or good second class honours degree or equivalent in Chemistry and have interests in total synthesis.

Salary, which includes payment for up to 6 hours per week teaching assignment is £5,910 — £6,657 per annum.

Closing date for applications: 31 July 1985.

An Equal Opportunity Employer

STUDENTSHIPS

INSTITUTE OF
PHYSIOLOGYUNIVERSITY OF GLASGOW
RESEARCH STUDENTSHIP

Leading to Ph.D. and commencing 1st October. The project, which is supported by the Foundation for Age Research, will investigate ageing changes in the human fovea by histological, electrophysiological and psychophysical methods. The appointee should possess a class 2(1) degree in a relevant subject and will be part of an active vision group with close clinical contacts. Applications (curriculum vitae with 2 referees) to Dr J. D. Morrison (Tel. 041 339 8855, ext. 499) as soon as possible. (7098)F

THE SCHOOL OF
PHARMACYUniversity of London
RESEARCH STUDENTSHIP
IN CHEMISTRY

A SERC case research studentship, in conjunction with Unilever plc, is available from October 1985 leading to a higher degree. The project involves the measurement of diffusion coefficients of macromolecular materials using classical and elastic light scattering techniques.

Applicants should have, or expect to obtain a good honours degree in Pharmacy, Chemistry, Biophysics or Physics.

Interested persons should contact: Dr R Fleming, The School of Pharmacy, 29/39 Brunswick Square, London, WC1N 1AX as soon as possible (7079)F

ROTHAMSTED
EXPERIMENTAL STATION
HARPENDEN,
HERTS. AL5 2JQSTUDENTSHIP: GENETIC
MANIPULATION IN
POTATO

Applications are invited for a Ph.D. Studentship at Rothamsted Experimental Station to study expression of RIT-DNA genes in potato and their effect on potato development. The project will involve molecular and cell biological techniques and the use of Agrobacterium to obtain transformed plants.

Candidates should hold a First or Upper Second Class Degree in Biology, Biochemistry or related subject.

Applications giving full c.v., the names of two referees and quoting Ref. 598 should be sent, not later than 30 July 1985, to Dr G Ooms, Biochemistry Department, Rothamsted Experimental Station, Harpenden, Herts. AL5 2JQ.

We are equal opportunities employers. (7095)F

UNIVERSITY OF
LEICESTER
POSTGRADUATE
RESEARCH IN PHYSICS
Ph.D.

Three S.E.R.C. studentships are available leading to the degree of Ph.D. in the following areas:

Theoretical Physics
(Hot electron dynamics in Quantum wells)
Ionospheric Physics

UNIVERSITY COLLEGE
CARDIFFDEPARTMENT OF PHYSIOLOGY
PhD STUDENTSHIP

Applications are invited for a Research Studentship in a project concerned either with: a) Synaptic interactions in the central visual system b) Modulation of sensory transmission through thalamic relay nuclei

The projects will take place in well equipped MRC funded laboratories and will offer access to a wide range of the latest techniques. Applicants should have a First or Upper Second Honours Degree in a relevant scientific subject. Those interested should apply to Professor A M Sillito, Department of Physiology, University College, PO Box 78, Cardiff CF1 1XL, enclosing a brief Curriculum Vitae and the names and addresses of two referees. Informal enquiries can be made to Professor Sillito by telephone on 0222 44211 Ext 2062, and potential applicants will be welcome to visit the laboratories (7025)F

CASE STUDENTSHIP:

Spectroscopic Studies of
Adsorbed Surfactant Molecules

This project, sponsored by Unilever Research, is aimed at the detailed study of the structure, arrangement and interactions of surfactant molecules chemisorbed on a variety of substrates ranging from metals to fabrics. Infrared and Raman studies will be combined with absorption isotherm and esr measurements to investigate the ways in which detergent molecules adhere to industrially relevant materials. Both molecule-molecule and molecule-substrate interactions are important and will be studied as a function of chemical (head group) properties, coverage and method of deposition. The work will be jointly supervised by Dr Jack Yarwood (at Durham) and Dr Kay Fox (at Unilever, Port Sunlight). The student will spend at least 4 weeks per year working at Port Sunlight and will receive £400 per annum (subject to satisfactory reports) in addition to the usual SERC grant.

Applications, naming a referee, from those who have (or expect to have) at least an upper 2nd class degree in chemistry should be sent as soon as possible to Dr J Yarwood, Department of Chemistry, University of Durham, South Road, Durham, DH1 3LE. (7066)F

(Radar studies of the auroral zone ionosphere)
Nuclear Electronics
(Microchannel plate development for X-ray space missions)

The studentships provide an opportunity of joining an active department engaged in research of fundamental and technological importance. Enquiries from graduates with a first or upper-second class honours degree should be sent to Professor E. A. Davis, Head of Department. (7106)F

PROPOSALS

OPEN CONTRACTING
FUND

Within its existing budget provision, the Ministry of Agriculture, Fisheries and Food intends to commission research projects in the following areas of concern, where practical solutions to specific problems are sought: viz, controlled droplet applicators, environmental factors in upland farming, odour treatment in intensive livestock operations, nitrate leaching, agriculture/forestry, efficient marketing of horticultural crops, transport of pigs to slaughter, streptococcal meningitis in pigs, nutritive value and palatability of double-zero rape meal, the relationship of instrumental methods to food sensory assessment methods, mechanical spectroscopy in food systems, and control of lipolysis in flavour development. Applications to carry out this work are sought from individuals or groups with proven research capabilities. These will normally be in University departments, research associations, research institutes or industrial laboratories.

Those wishing to develop proposals should write for further details to Mr P. F. Slack, Ministry of Agriculture, Fisheries and Food, Room 117, Great Westminster House, Horseferry Road, London SW1P 2AE.

The closing date for submissions will be Monday, September 16th, 1985. (7089)X

UPDATE IN MOLECULAR BIOLOGY 1985 Genes and Systems in Development

Presented in association with the University of California at San Francisco
OCTOBER 7, 8, 9, 1985 SHERATON-PALACE HOTEL, SAN FRANCISCO

PERHAPS THE MOST IMPORTANT CONFERENCE YOU'LL ATTEND THIS YEAR! featuring preeminent scientists on the frontiers of uncovering new genetic techniques that will aid in understanding the development of micro- and macro-organisms.

NATURE's conference will keep you abreast of the very latest discoveries in... the diagnosis and therapy of genetic defects, oncogenes, homoeotic genes, yeast development, the immune system, and the development of neural systems.

MEALS WILL BE AWARDED!

ATTEND OUR GALA CONFERENCE DINNER on Tuesday, October 8, in the historic, glass-domed Garden Court. Admission only \$29.50 per person.

POSTER SESSIONS will be held each day. For consideration, please send working title and brief synopsis to Posters Editor, Nature Publishing Company, 65 Bleeker Street, New York, NY 10012.

MEET SPEAKERS AT ROUNDTABLE DISCUSSIONS HELD EACH AFTERNOON and have ample opportunity to present your own ideas.

ROOM RESERVATIONS: Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Please mention your participation in the Nature 1985 conference to qualify for special rates.

GRANT PROGRAM for selected graduate students to be announced during August 1985.

YOUR REGISTRATION FEE could be tax deductible!

A MAJOR EXHIBITION of scientific products and services will be held in conjunction with the conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

SYSTEMS

Speakers	Topics
F. Bloom (Research Institute of Scripps Clinic)	Vertebrate neural systems
J. Gerhart (U. of California at Berkeley)	Early development—Xenopus
C. Nüsslein-Volhard (Tubingen)	Early development— <i>Drosophila</i>
C. Goodman (Stanford)	Development of invertebrate neural systems
H.R. Horvitz (MIT)	Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers	Topics
M. Davis (Stanford)	T-cell receptors

U. Storb (U. of Washington at Seattle)	B cells
J.M. Bishop (U. of California at San Francisco)	Oncogenes
M. Ptashne (Harvard)	Regulatory proteins
I. Herskowitz (U. of California at San Francisco)	Yeast development
E. Jaworski Monsanto	Plant transformation

DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers	Topics
R. Palmiter (U. of Washington at Seattle)	Transgenic mice
D. Hogness (Stanford)	<i>Drosophila</i> homoeotic genes
W. McGinnis (Yale)	Mammalian homoeotic genes
T. Friedmann (U. of California at San Diego)	Human therapy
To be announced	

*Additional speakers will also appear on the program

TO REGISTER FOR THE CONFERENCE

Return this form with your check, credit card authorization or an authorized purchase order to: Nature Update in Molecular Biology, Nature Publishing Company, 65 Bleeker Street, N.Y., N.Y. 10012

Sequence regions Klenow can't!

**With Bio-Rad
Reverse Transcriptase.**

Bio-Rad's reverse transcriptase is qualified for dideoxy sequencing on single-stranded DNA templates. The data shown here demonstrates the high quality sequence pattern generated with this product. Furthermore, the reactions were performed using minor modifications of standard Klenow sequencing protocols

Autoradiograms of 8% sequencing gels comparing the products of oligodeoxynucleotide-primed sequencing reactions from the same recombinant M13 single-stranded DNA template using Klenow fragment (Panel A) or Bio-Rad reverse transcriptase (Panel B). The reaction conditions for reverse transcriptase are identical to those for the Klenow except for the following: 40mM NaCl added, incubation temperature raised from 25°C to 37°C, and concentrations of ddNTPs lowered relative to dNTPs.

The four regions that were sequenced unambiguously with reverse transcriptase but not with Klenow are labeled I through IV and indicated with brackets. Data provided by Dr Robert F Fisher, Department of Biological Sciences, Stanford University

We, and others, have found that reverse transcriptase sequences certain stretches of DNA in an unambiguous manner that the Klenow enzyme does not sequence cleanly. For example, Panel B shows a 70 nucleotide stretch of an M13 recombinant DNA template containing four major regions that Bio-Rad's reverse transcriptase sequenced properly—but Klenow did not. It's apparent that reverse transcriptase serves as a valuable complementary reagent to Klenow for dideoxy sequencing. In order to maximize your sequencing rate, your laboratory should consider using both enzymes:

For additional data demonstrating the utility of Bio-Rad reverse transcriptase in dideoxy sequencing of DNA, as well as complete protocols for performing the sequencing reactions, ask for Bulletin 1205.

SCIENCE IN
AUSTRALASIA

No other densitometer looks bigger and better

Big enough to handle whatever electrophoresis gels you're using. With better results to match your work. That's LKB's new laser densitometer. UltraScan XL looks at all types and formats, up to 22×25 cm, wet or dried. With increased capacity and faster scanning, this big all-rounder gets more work done in a lot less time. And its straight-as-a-laser beam delivers an unrivalled $50 \mu\text{m}$ resolution with a linear range of 4 OD. Now you can really penetrate closely stacked bands and uncover a wealth of data. Multiple scanning of every sample track gives you reliable average measurement across each protein zone. And when you want fast quantitation by simple programming, the onboard integrator delivers. The scan together with area calculations are presented directly to a standard dot matrix printer. It couldn't look better.

But don't be deceived by good looks alone. UltraScan XL comes with brains as well. The onboard computer lets you exactly define track position and fields of interest, and then automatically scans up to 99 tracks – any way you decide. With gels containing zones of varying intensities from track to track, the unique normalization program lets you compare all your samples in just one run. And talking about comparison, take a look at the large screen monitor. Just tell UltraScan XL what you want, and your video shows you every decision, every command and even a few wishes. Like interfacing with your favourite computer. Or running your own software. You'll evaluate, store, manipulate, display and present your results better than ever.

All in all, it looks like you're getting yourself a scanner that's bigger and better from every viewpoint. Style. Performance. Value. It's worth looking at. Today!

PEPTIDE ANTISERA

CRB has considerable experience in the preparation, purification and conjugation of synthetic peptides for use in the preparation of anti-peptide antibodies.

To complement our range of biologically active peptides CRB offers:

POLYCLONAL PEPTIDE ANTISERA

Fully characterised for radioimmunoassay		Designed for and tested by immunocytochemical techniques	
Antisera raised to		Antisera raised to	
ANP	Bombesin	Bombesin	CCK-8
Calcitonin	Katacalcin	CCK-39	Leu-Enkephalin
CGRP	CRF	Met-Enkephalin	FMRF-amide
CCK	Leu-Enkephalin*	GIP	Glucagon
Gastrin	GIP	Motilin	NPY
Glucagon	Motilin	Neurotensin	PHI
Neurotensin	NPY	Somatostatin 14	Somatostatin 28
Oxytocin	PHI	Substance P	VIP
Secretin	Somatostatin		
Substance P	VIP		
Arg-Vasopressin			

*A new antiserum for the specific measurement of Total Enkephalins and/or Leu-Enkephalin and/or Met-Enkephalin. The antigen has been prepared by a new methodology resulting in a conjugate of

Leu-Enkephalin with BSA via 4-position of enkephalin residue 1 (see Marley *et al.* Neuropeptides 4, 477 (1984))

Each product is supplied with a data sheet giving information on specificity and recommended assay protocol and staining procedures for radioimmunoassay and immunocytochemistry respectively.

For further information please ask for our Peptide Antisera 1985/86 Catalogue which gives details of the complete range.

NOW THAT'S
WHAT I CALL
GENETIC
ENGINEERING

They say that good breeding shows and when you look at our latest generation of microplate readers you'll have to agree. Descendants of the original Titertek®. Multiskan, the first "through-the-plate" reader, they have inherited its characteristics of quality, strength, speed and reliability, evolving into a family of instruments each bred to be the leader in its field.

Titertek®-Miniskan
Single-channel photometer for microstrips with digital display and integral computer interface. Reads in manual or automatic mode.

Titertek®-Fluoroskan
Combining the sensitivity of fluorescence with the convenience of microplates. Utilizes standard microplates (no special coloured plates required). Two operational modes with display of absolute or relative reading.

Titertek®-Multiskan MCC/340
Computer-controlled, multi-chromatic 8-channel photometer. Wavelength range from 340 to 750 nm, with built-in operational modes for stand-alone use.

Titertek®-Uniskan
Single channel photometer from 340 to 750 nm. Complete with three interference filters, printer and integral computer interface.

Titertek®-Multiskan
8-channel photometer. Reads all 96 wells of microplates in under 60 seconds. 2 operational modes with print-out in absorption or matrix-format.

Titertek®-Twin-reader
Single-channel fully automatic programmable photometer. May be used alone with its integrated programmable reading modes or be fully computer-controlled. Temperature control, kinetic capability and dual plate capacity make this machine suitable for clinical chemistry.

AuroDye

HI-TECH SCIENCE DEMANDS PERFORMANCE

AuroDye is a new and powerful stain for proteins on nitrocellulose membranes. It is at least twenty times as sensitive as Coomassie Blue or Amido Black.

AuroDye is economical and simple to use.

AuroDye consists of negatively charged colloidal gold particles in an environment which optimizes their protein-binding capacity.

AuroDye gives you the sensitivity which matches that of our new ImmunoGold Silver Staining immunodetection technique.

Please contact us for more information on this revolutionary product and its world-wide distribution network.

Reader Service No.19

Rapid detection of single copy genes

with our SP6 System and SP6 Grade ribonucleotides

Amersham's new SP6 System and SP6 Grade ribonucleotides give you:

- **Sensitive detection:** RNA hybridization probes of $\sim 1.3 \times 10^9$ dpm/ μ g using our SP6 Grade [α - ^{32} P] UTP, code PB.20383 or SP6 Grade [α - ^{32} P] CTP, code PB.20382 (~ 800 Ci/mmol).
- **Convenient formulation:** above products are specifically designed at high radioactive concentration (20 mCi/ml) to be used directly from the vial. Fresh batches are prepared and tested weekly.
- **Choice of label:** for ^{35} S-labelled RNA probes we offer SP6 Grade [α - ^{35} S] UTPaS, code SJ.263 (> 400 Ci/mmol at 10 mCi/ml) giving probe specific activities of $\sim 6.7 \times 10^8$ dpm/ μ g.
- **Complete reliable system:** our SP6 System, code RPN.1506, contains all the major non-radioactive components required for up to 50 probe preparations or 20 RNA generation reactions using our tried and tested protocols. Reagents are rigorously tested to ensure consistent high performance.

Unparalleled commitment to your research

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

Reader Service No.25

SCIENCE IN AUSTRALASIA

Australia and New Zealand are most alike in their great distance from everywhere else. Both maintain scientific establishments comparable with those of Europe and North America. In *Nature's* special Australasian issue, Alun Anderson and John Maddox describe their special problems and particular achievements in research and development, and recommend what should be done.

Copies of this special issue are available now.

Australian orders should be sent to:

John Rosenbloom, Macmillan Co. of Australia Pty Ltd, Locked Bag 12, South Melbourne 3205, Victoria, AUSTRALIA. Telephone (3) 6998922.

Please enclose remittance of A\$6 per copy.

Prices and order address for other countries are set out below.

Annual Subscription Rates (including Index)

USA & Canada US\$230

WHAT IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

**OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL
SAN FRANCISCO, CALIFORNIA**

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: **How is the process of development directed by genes?**

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homoeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.

Full 3-day registration fee: \$375.00

Pay only \$325.00 if you register before July 31.

LOCATION

The Sheraton-Palace Hotel located at 639 Market Street

is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: \$95. Doubles: \$105 and \$115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

**YOUR REGISTRATION FEE
COULD BE TAX DEDUCTIBLE**

CONFERENCE DINNER

Our gala Conference dinner will be held Tuesday, October 8, in the historic, glass-domed Garden Court. To insure seating, please include your dinner ticket requirements and payment of \$29.50 per person with your registration.

EXHIBITS

A major exhibition of scientific products and services will be held in conjunction with the Conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

SYSTEMS

Speakers

F. Bloom
(Research Institute
of Scripps Clinic)

J. Gerhart
(U. of California
at Berkeley)

C. Nusslein-Volhard
(Tübingen)

C. Goodman
(Stanford)

H.R. Horvitz
(MIT)

Topics

Vertebrate neural
systems

Early development—
Xenopus

Early development—
Drosophila

Development of
invertebrate
neural systems

Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers

M. Davis
(Stanford)

U. Storb
(U. of Washington
at Seattle)

J.M. Bishop
(U. of California
at San Francisco)

M. Ptashne
(Harvard)

I. Herskowitz
(U. of California
at San Francisco)

E. Jaworski
Monsanto

Topics

T-cell
receptors

B cells

Oncogenes

Regulatory
proteins

Yeast
development

Plant
transformation

DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers

R. Palmiter
(U. of Washington
at Seattle)

D. Hogness
(Stanford)

W. McGinnis
(Yale)

T. Friedmann
(U. of California
at San Diego)

Topics

Transgenic mice

Drosophila
homoeotic genes

Mammalian
homoeotic genes

Human therapy

*Additional speakers will also appear on the program.

**SAVE \$50
IF YOU
REGISTER
BEFORE
JULY 31!**

START 1986 WITH A LOOK AT 1996

BIO/TECHNOLOGY'S PREMIER CONFERENCE

Whether you're an R&D Project Manager, VP of Research, a Senior Scientist, a Process Engineer, Department Chairman or an Academic Researcher—this is one conference you can't afford to miss.

For our first conference, we've planned three days of free-wheeling discussions with researchers and research managers who set the pace in biotechnology. You'll learn about up-to-the-minute developments in the world of molecular biology and you'll get a jump on the ideas and techniques that will guide biotechnology through the '80s and '90s.

Participation is limited. So don't delay. Register now to guarantee your place.

Location: Clarion Hotel, 1500 Canal St., New Orleans, LA 70112

Room Reservations: Rooms can be reserved directly with the hotel by calling 1-800-362-6000 or 1-504-522-4500. Be

certain to reserve early a participation in the BIO/T CONFERENCE to take a special convention rates \$60, \$68, \$75, \$80. Doubles \$63, \$70, \$78, \$85, \$90

Poster Sessions: Scientists come to submit abstracts commercial applications presentation. Mail abstracts to BIO/TECHNOLOGY, 65 E New York, NY 10012

Exhibits: An exhibit of instrumentation and separation instrumentation, and other related to biotechnology will

To Register: Return the check, credit card authorization or purchase order

JANUARY 20, 21, 22, 1986

CLARION HOTEL NEW ORLEANS

CONFERENCE PROGRAM & SPEAKERS

JANUARY 20—MORNING

The Molecular Biology of Plants and Animals: A View From the Frontier

Speakers

Richard Flavell, President, Biogen Research Corp

David Goeddel, Director, Molecular Biology, Genentech

Norman Borlaug, CIMMYT, Mexico City and Professor, Dept. of Soil and Crop Science, Texas A&M

JANUARY 20—AFTERNOON

Seminar in Molecular Biology

David Goeddel, Co-Chairman

Richard Flavell, Co-Chairman

Budd Colby, Director, Technology Development, Triton Biosciences

Seminar in Agricultural Biotechnology

Norman Borlaug, Chairman

Robert Fraley, Manager of Plant Molecular Biology, Monsanto

David Evans, Vice President for Research, IMA Plant Technology, Inc

Charles Arntzen, Associate Director of Central Research and Development, E. I. du Pont de Nemours and Co.

JANUARY 21—MORNING

Commercial Production Processes

Speakers

Malcolm Lilly, Professor of Chemistry and Biochemical Engineering, University College, London

Robert Herschberg, Department of Process Development, Genentech

Yukio Sugino, Director, Biotechnology Labs, Akeda Chemical, Japan

Ephraim Katchalski-Katzir, Professor of Biophysics and Biotechnology, Tel Aviv University, Israel

JANUARY 21—AFTERNOON

Seminar in Scale Up

Malcolm Lilly, Co-Chairman

Robert Herschberg, Co-Chairman

Garry Buckland, Director, Computerized Pilot Plant, Merck, Sharp, & Dohme

Stanley Tarnowski, Research Section Chief, Dept. of Bioseparations, Hoffmann-La Roche

Seminar in Fermentation

Yukio Sugino, Chairman

Arnold Demain, Director of Laboratory of Fermentation and Microbiology, MIT

Behzad Khosrovi, Senior Director, Process and Product Development, Cetus Corp

William Tolbert, Research Fellow, Monsanto

Seminar in Immobilization & Biocatalysis

Ephraim Katchalski-Katzir, Chairman

Allen Laskin, Industrial Consultant, Chairman, BIO/TECHNOLOGY Scientific Board

Gary Calton, President, Purification Engineering, Inc

JANUARY 22—MORNING

Innovations in Pharmaceuticals & Immunology

Speakers

Bernard Moss, National Institutes of Health

Emil Thomas Kaiser, Haggerty Professor, Rockefeller University

George Poste, Vice President and Director of R&D, Smith Kline & French

JANUARY 22—AFTERNOON

Seminar in Vaccine Development

Bernard Moss, Chairman

Pablo Valenzuela, Vice President of Research, Chiron Corp

Mark Greene, Professor, Dept. Harvard Medical School

Seminar in Peptide Design

Emil Thomas Kaiser, Chairman

Gregory Winter, MRC, Mill Hill

Gregory Petsko, Professor, MIT

Seminar in Drug Delivery

George Poste, Chairman

Joseph Robinson, Professor, Univ. of Wisconsin

Colin Gardner, Director of Biological Research, Inter X, a Merck & Company

Now you can synthesize DNA by β -cyanoethyl amidite or phosphotriester chemistries on a single system.

The Model 8600 DNA Synthesizer from Biosearch is preprogrammed for both synthesis protocols. Choose the one best suited to your needs and optimize DNA fragment length or synthesis cycle time.

If your requirements call for long DNA fragments, Biosearch's β -cyanoethyl amidite chemistry makes it possible to synthesize fragments well in excess of 150 bases with 250 O.D. or more of product—and a cycle time less than 6 minutes. These long fragments can be used to synthesize whole genes more easily by reducing the number of enzymatic ligations required, with a concomitant decrease in the number of purification steps.

Electrophoresis gel results for 150-base polynucleotide synthesized by β -cyanoethyl amidite chemistry

On the other hand, if your need is for rapid, economical short-chain syntheses, Biosearch's new optimized phosphotriester chemistry can simplify the routine synthesis of oligonucleotide fragments up to 50 bases. You can expect reliable results in a cycle time of less than 7 minutes, with fewer steps and fewer reagents utilized.

And you're not limited to these two protocols. Since the 8600 is fully programmable, you can modify stored chemistries or develop your own as required. This

flexibility will allow you to keep abreast and take advantage of new advances in DNA synthesis.

Electrophoresis gel results for 35-base oligonucleotide synthesized by optimized phosphotriester method

Whatever method you choose, you'll find that the 8600 makes it easier to obtain higher yields and faster cycles with automated mixed probe synthesis, automatic deprotection and cleavage, and simultaneous, four-column synthesis.

Biosearch also provides high-purity, high-stability reagents for both β -cyanoethyl amidite and phosphotriester chemistries. Moreover, each 8600 system is supported by a worldwide network of experienced technical personnel.

Biosearch—better ways to synthesize biomolecules.

What price depleted uranium?

A few weeks before the third review conference of the Non-Proliferation Treaty (NPT), it is disturbing that large quantities of depleted uranium have been sold without safeguards.

A MONTH from now, the signatories of the Non-Proliferation Treaty (NPT) will be gathering at Geneva for a conference to review the terms of the treaty. If this conference follows the two earlier meetings of its kind (1975 and 1980), there will be diplomatic ructions. Even though, by all accounts, preparations have been carried out more smoothly than those for previous conferences, it is probably asking too much of the non-nuclear powers that they do not question the precious little progress that the nuclear powers have made towards their promise under the treaty to negotiate measures of strategic arms control "in good faith". On past form, but also with some reason, non-nuclear powers will argue that more should have been done to spread the civil benefits of nuclear technology. But what will they, and even the nuclear powers which have signed the treaty, make of the puzzling news last week that companies in Luxembourg and Belgium have supplied to Israel several tonnes of depleted uranium in the fissile isotope uranium-235, and that Euratom, Europe's own safeguards authority, was not informed?

It is tempting to think that uranium metal consisting primarily of uranium-238, a waste material in isotope separation plants, has no military significance. Since the first huge hydrogen bomb explosions on the Marshall Islands in the Pacific during the 1950s, it has been clear that ordinary uranium of any isotopic composition may be useful to those who would increase the yield of their explosions. To make a uranium fission-bomb, or a uranium trigger for a hydrogen bomb, it is of course necessary to rely on uranium-235, whence all the fuss about diffusion plants, centrifuges and, now, lasers as a means of separating this isotope from the two others that naturally occur. But in a hydrogen bomb, in which a thermonuclear explosion is ignited by a fission trigger, a surrounding shell of material consisting of heavy atomic nuclei will enhance efficiency by reflecting back into the explosion neutrons that would otherwise escape. Using uranium-238 as the external blanket has the further virtue, if that is the word, that a proportion of the material will undergo fission under the influence of fast neutrons from the explosion. All this was inferred, as long ago as 1955, by Dr Joseph Rotblat using data about the composition of fall-out from the Eniwetok explosion of 1952.

The fact that somebody in Israel has been buying depleted uranium does not, of course, imply that somebody in Israel is interested in making dirty hydrogen bombs. There are many other obvious uses for uranium-238, most of them deriving from its high density and its relative cheapness. But given the trouble that Israel has taken over the years to create the impression that it has gone a long way down the road to the manufacture of nuclear weapons, it is inevitable that suspicions will be aroused. Israel after all, is not a signatory of NPT. Whatever may be the use to which the uranium will be put, however, the fact remains that the sale from the Low Countries to Israel has been made

without the knowledge of Euratom, which has a special status in relation to the international safeguards system in that it has delegated authority from the International Atomic Energy Agency, NPT's inspector, to vouch for what happens within the European Communities to special nuclear materials. The issue has in the past been contentious: why, other members of NPT have asked, should European countries be able to make cosy relationships among themselves without direct invigilation from Vienna? Although it is not quite like that, in that Euratom safeguards are probably at least as demanding as those administered from Vienna, the members of NPT are likely to ask awkward questions about the lapse that came to light last week.

Confidentiality

What should be done? The members of Euratom have a vested interest in demonstrating that their hands are clean, and should do what they can in the next few weeks to show that that is the case. No harm would be done, even after the event, if the companies now found to have been selling depleted uranium on a commercial basis were to be asked, even compelled, by their governments to ask their customers what had become of it. Even if it should be discovered that the customers do not know, or will not say, what is being done with the depleted uranium, that will be useful information, which should of course be made available to the members of NPT. If it should turn out that the users can point to good reasons why they were buyers in the first place, and to the ways in which they are putting the material to good use, that too would be valuable information. The selling companies will no doubt say that such information, being commercial, is also confidential, but that is hardly an argument that should carry much weight; the sellers are, after all, those who have broken the law.

In the past few days, Euratom has clearly been hoping that the sale of the depleted uranium would be quietly forgotten; the names of the selling companies, for example, have not been disclosed. Similarly, no convincing explanation has been given of the source of the material sold, although there are only a few places from which it could have come (the diffusion plants in Britain and France, and the tripartite centrifuge enrichment operation involving Britain, the Netherlands and West Germany in Eurenco). It would be interesting, even significant, to know what Euratom has to say on this question, at the very least because a willingness to abide by the rules on the part of the legitimized uranium enrichment operations involving nuclear powers is an essential precondition of Euratom's chance of continuing to hold delegated authority for safeguarding what happens in Europe.

On the face of things, all this may seem irrelevant to what the NPT review conference will be considering at Geneva — a little local difficulty, so to speak. But that is far from the truth. NPT is already a sufficiently uneasy balance between powerful countries with nuclear weapons and often equally powerful countries that have agreed, for everybody's sake, that they will not go into the business. Transgressions, however small and accidental by the nuclear powers or their agents (those who sell their depleted uranium) could ironically be more unsettling than the errors (mostly of omission) at which the non-nuclear signatories now rail — in particular, the poverty of progress in arms control. □

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, it will be helpful if they will in future send **four copies of all manuscripts** offered for publication, either (as at present) to London or Washington.

British politics

Mrs Thatcher asks for decisiveness

Mrs Margaret Thatcher, the British Prime Minister, remains convinced that the British research establishment would have no money problems if it managed its affairs properly. That was one of her opinions on the condition of British science to emerge from an interview last week.

Formally, since the government in 1982 rejected the House of Lords' advice that there should be a part-time science minister on the grounds that it already had a scientist as a prime minister, hers is the desk on which the buck stops. How much time can she spare for it?

Coordinating departments straddling different interests are a mistake, she says, the Cabinet Office in the person of the Chief Scientific Adviser, Sir Robin ("Robin has been wonderful") Nicholson does whatever administrative coordination is needed, and her role is that of a catalyst. She lists the open seminar in September 1983 of scientists and industrialists (with a sprinkling of politicians) of which she was the chairman, and several more recent initiatives. She seems especially pleased about the meeting earlier this year at which £42 million was extracted from the spending departments to assist the growth of numbers of science and technology students in higher education.

One outcome of the 1983 seminar, at which she promised that innovations supported by the public purse would not be offered for exploitation exclusively to the National Research Development Corporation (now part of the British Technology Group) has now been realized. Mrs Thatcher cannot understand why there was so much red tape to clear away. She had wanted individual scientists to benefit more directly from their innovations, but had had to struggle to get her way.

What of the other promise, in 1983, that British defence establishments would be made more open, both to universities and industry? There is some confusion. The defence people have produced an unsatisfactory list of civil spin-off from military research and have been asked to revise it. Fair play, the defence people now have a kind of entrepreneurs' organization of their own.

Wealth creation is the name of the game. Mrs Thatcher says that scientists must appreciate that money for research can come only by the creation of wealth, for which they have a responsibility. But things are not as bad as they seem. She could name a dozen teams of academics pointing in the right direction (and, indeed, she embarks on a list).

On the research councils, she insists that people must be prepared to put their

wishes in some order of priority. Complaints that first-class applications for research grants now often go unsupported are a sign that this is not happening. "People are not prepared to make decisions", she declares.

Mrs Thatcher is also offended at the way research councils administer their affairs. Applicants are asked to include three supporting opinions with their ap-

plications, but then "they send out for another three opinions", which is yet another sign that people are not prepared to take decisions. Why not instead give good institutions a quota of grants and let able professors decide who should get the money? Then the research councils could spend all their administration costs on research.

Reflectively, Mrs Thatcher wonders whether previous governments should not have been more "directional". During the university expansion of the 1960s, people may have been too conscious that the University Grants Committee is independent. The result was that too much of the expansion took place in the social sciences, not science and technology. And where else in the world does the government subsidize business schools?

Now she wants to see more centres of excellence in the universities. The trouble in the past has been that "we've not backed our judgement with money". This is what the University Grants Committee is now aiming at. (Sir Peter Swinnerton-Dyer, its chairman, is also "doing a very good job".) But Mrs Thatcher gives the impression that the recent green paper on higher education will not be her government's proudest achievement.

Mrs Thatcher also thinks it may have been a mistake to leave the judgement of what lines of research would be supported exclusively to the research councils. Earlier (as Secretary of State for Education and Science in the early 1970s), she had supported British high-energy physics. But now she wonders why the research councils are spending so much in this field when the same amount of money would

allow them to do much more elsewhere.

She has little sympathy for the research councils now short of research funds because of having to persuade people to retire early. They have not organized themselves for flexibility. "The worst thing you can do in research" is to put able people in narrow institutes; then "they work on tramlines".

The problem, as she sees it, is that of persuading the research councils to spend their money wisely. They have a "bounden duty" to take responsibility. Now, some people in the research establishment are beginning to do their duty. Sir Henry Chilver (director of the Cranfield Institute of Technology) is one, Dr John Ashworth (vice-chancellor of the University of Salford) is another. Mrs Thatcher contrasts these places, which are "creating jobs" with the other universities, in Manchester and Liverpool, where "we have these huge problems".

On the better exploitation of academic innovations, Mrs Thatcher agrees that industry may in the past have been at fault. People had to hawk their bright ideas around industry, often to no avail. But, she insists, the climate has now changed. It has taken a long time to get managers into a frame of mind to take decisions.

Mrs Thatcher praises the enterprise of the Victorian industrial revolution, acknowledges that one consequence may have been to divert large numbers of bright people into the administration of the old Empire, but says that, now, "the particular combination of genius that we have is not creating the wealth we need. Give me just one MIT", she pleads.

Mrs Thatcher's impatience is understandable, with the money supply once more out of balance. What will happen in the months ahead to the British government's research budget, and the recurrent grant for the universities, can only be a guess. But those who hope for extra funds probably hope in vain.

John Maddox

Informatik stretched

Bonn

THE Westdeutsche Rektorenkonferenz (WRK), official organization of the West German university rectors, has asked for tighter restriction of student access to courses in information sciences (*Informatik*). At their plenary meeting last week, the rectors pointed out that these new courses are overloaded by 200 per cent.

The president of WRK, Theodor Berchem, criticized the decision of the *Länder* (regional governments) to keep these courses open to general access. Part of the trouble is that the number of qualified professors for information sciences in West Germany is too small to cope with the demand. About 50 vacancies have not been filled, and for the planned 4,000 beginners (instead of 2,400 now), 100 additional positions for professors are needed.

Jürgen Neffe

Eureka

France optimistic on meetings

BRITAIN and France are coming closer together on issues of European science and technology policy, to judge by the impressions of M. Hubert Curien, the French Science Minister, of his flying visit to Britain last week.

"I was glad to see we all agree very closely on Eureka" said Curien, after an afternoon with Sir Keith Joseph, British Secretary of State for Education and Science, and Mr Geoffrey Pattie, Minister for Information Technology. Eureka, the French project to develop a series of new high-technology European products from supercomputers to genetically engineered seeds (see *Nature* 11 July p.97), is the subject of a 17-delegation European conference in Paris this week, and Curien was certainly interested during his British visit to test Britain's opinion after British isolation on issues of wider European integration at the recent summit in Milan. He left London "much more optimistic", and undismayed by reports that the British government is interested in Eureka only if it costs no new money. Anyhow, Eureka could start with only very meagre cash support, Curien intimated, but would not commit himself to precise figures for fear of prejudicing this week's meeting.

Out of the Paris meeting, Curien is seeking three things. First, an agreement on the principles of Eureka (that should be "no problem"); second, to produce a dossier of the interests of each country in the various "broad fields" of Eureka; and third and most difficult, to define a structure in which Eureka should be managed.

Curien was adamant last week that Eureka should not fall into the embrace of the European Commission. He would like to see a "very light" structure, although he said at a lunchtime meeting at the London-based Policy Studies Institute (PSI) that to avoid bureaucracy altogether could prove "idealistic". The European Commission could not manage Eureka because it had never produced products, and Eureka was strictly product-oriented, he said. The Commission's ESPRIT programme on stimulating cooperation among European companies in pre-competitive research in information technology is a success, but it stops at pre-competitive research — precisely because it is difficult at the Commission to reach unanimous agreement in the European Council (the Commission's political master) on real and potentially competitive products.

Curien is a past president of the French space agency CNES which designed, built and tested Ariane, Europe's space launcher, and naturally he sees the success of Ariane as a model for Eureka. The European Space Agency, which commissioned Ariane, had adopted in 1973 a policy of projects "à la carte". Ariane went ahead only because the French wanted it pas-

sionately: they paid two-thirds of the development cost, while Britain stood aside. "If it had been a mandatory programme we would have had no Ariane." Equally, Germany (with Italy) had shouldered most of the burden of developing Spacelab, and Britain had put 50 per cent support into the European Communications Satellite, ECS.

Such projects could not have taken place within the Commission structure, Curien felt, because of the present requirement for unanimity in the Council of Ministers. "The result is always support for the least offensive programme", Curien said, and it is "difficult to be ambitious" within the European Communities structure. (Ironically, the often ambitious Commission officials would certainly agree, faced as they often are by the immovable political obstacle of the Council of Ministers.)

Curien sees the future Eureka management as an "industrial" structure, focused on making things, which should be selected on technical merit and not political representation, Curien insists. And he

agreed with Sir Hermann Bondi, chairman of the PSI meeting, that Eureka will need a technical group "of a quality respected by industry". But "I don't want 17 representatives on everything", one from each state, says Curien.

Asked how Eureka projects would be chosen, Curien emphasized the need for specific, practical projects: "if we just say 'robotics' that would be useless"; but he was less insistent on the need to identify a market for each product. He seemed to be thinking largely along the lines of other major French government-led successes such as the high-speed train and nuclear power, and thus of government purchasers. He admitted, however, that both government and the free market must be considered.

Curien did not expect the Paris political meeting this week to define specific projects — that would be for working groups involving industry later on, once the political ground rules had been settled. However, he did hope to see "five or six" projects under way by the end of this year.

The 17 delegations should consist of the 12 European Community countries, plus Norway, Sweden, Austria, Switzerland and a delegation from the European Commission

US ASAT

Live test tactfully postponed

Washington

A PLANNED July test of the US antisatellite (ASAT) weapon against a live target in space has been delayed yet again, and is unlikely to be rescheduled before Congress renews a moratorium on such tests. The previous moratorium expired in March.

The official explanation for the delay is a technical problem with the instrumented target, designed to simulate the infrared radiation of a Soviet satellite and to monitor the ASAT's performance. The targets have been returned to their manufacturer, Avco Systems, for repairs.

According to congressional staff, however, problems with ASAT itself persist as well. Last December, the Air Force was seeking bids on a contract for the redesign of ASAT's manoeuvring propulsion package, an array of 57 miniature solid-fuel rockets that steers the 12-inch-long, non-explosive projectile into its target. One problem mentioned then was motor exhaust contaminating the infrared sensors that lock onto heat radiation from the target. The failure to resolve these problems is thought to have led the Air Force to delay the test scheduled for July; the ASAT has been returned to its manufacturers, LTV Corporation.

Under current law, the test against a target could proceed if the President certifies to Congress that the test is necessary to avert irrevocable damage to

national security, that it would not damage prospects for negotiating a treaty limiting ASATs, and that the administration is trying to negotiate such a treaty.

The House of Representatives last month passed an amendment to the 1986 defence bill that allows tests only if the Soviet Union tests first a dedicated ASAT system against a target in space. The Senate has adopted a weaker amendment, requiring only presidential certification of his efforts to negotiate a treaty. The US ASAT has so far been fired only at an imaginary target in space.

One suspicion all along has been that the delay in testing against a target, although originally the result of technical problems, has been dragged out for diplomatic reasons.

US officials made it known last week that Soviet negotiators in Geneva have informally proposed dropping their insistence on an end to Star Wars research as a precondition for any new arms-control agreement.

The Soviets are said to be willing to draw a distinction between laboratory research, which could continue, and development and field testing, which would be banned. The Soviet delegates were said to have singled out the US ASAT tests as one example of actions that would not be allowed. The Soviets are expected to submit this new position in a formal proposal shortly.

Stephen Budiansky

UK energy

Department puts money on wind

THE British government, which in 1975 spent £0.5 million on renewable energy research, has since taken a wait-and-see attitude towards unconventional sources of energy. Now, backed by reports from the Advisory Council on Research and Development for Fuel and Power (ACORD), it seems to be coming off the fence. Technologies that the Department of Energy (DOE) calls "winners" — wind, solar, biofuels and geothermal hot dry rocks — will be financed for further research and development, but "less promising" options, notably the £17 million research programme into wave power, will be halted until further notice.

Mr David Hunt, the DOE minister responsible for renewables, earlier this month defended both the amount of government spending and its choices. This year, £14 million has been earmarked for renewables research which, Mr Hunt pointed out, should be increased to £20 million from European and other sources. He claims that these figures demonstrate a commitment to renewables as part of the energy grid.

Questioned whether the increase of cash spending from £16 million in the five years 1975–80 to £68 million in 1980–85 may mask a decrease in commitment, Mr Hunt said that renewables technology "stands up for itself" and should not be judged in terms of the spending on other energy sources. In any case, he claims, the government's programme is "the most positive commitment by any [British] government" to renewable energy sources.

Backing the winners — and wind is "no doubt the most promising" — will mean that more money is channelled into the technologies that ACORD and DOE have labelled as "economically attractive" or "promising but uncertain", and which may make a significant contribution by 2025. Technologies judged less viable, such as converting wave energy into a more usable form, will not be funded but DOE will monitor developments abroad and be ready to change tack. Mr Hunt urged members of the renewable resources community to look beyond their hobbyhorses and to accept the commercial common sense of backing such sources as wind, in which Britain enjoys "world-beating" technology. Only then would these technologies be got "out of the research stations, off the drawing boards and into our daily lives".

ACORD's enthusiasm for wind reflects world optimism, especially in the United States, where wind turbine farms already generate a significant amount of energy. DOE plans to concentrate on large-scale machines, both horizontal and vertical axis, and emphasizes the export possibilities as well as the generation of energy for remote areas of Britain. Research ex-

penditures in 1984–85 of approximately £4.5 million were roughly double those of the previous year; £6 million is budgeted for 1985–86.

The significant British milestones are at Bugar Hill in Orkney and at Carmarthen Bay. At Orkney a 250kW horizontal axis machine, built as a prototype, has operated for 2,303 hours and generated 212,533 kWh; now a 60m diameter 3MW horizontal axis turbine has been approved for the same site. Work at Carmarthen Bay has centred on building a multi-megawatt vertical axis turbine. ACORD estimates for 2025 suggest a 1.6 million tonnes of coal equivalent (Mtce) a year contribution from such onshore sites. Offshore development is still at a theoretical stage, but plans for both national and international projects are afoot.

DOE is also backing passive solar energy, the direct solar heating of buildings, a potential winner that "makes good economic sense". The private sector, according to Hunt, will be encouraged to design buildings that "make the most of sun shine", thereby cutting heating and lighting costs by as much as 30 per cent. ACORD describes passive solar design as a technology that "has come to fruition and is ready to enter the market".

Unlike wind energy projects, in which many technical obstacles impede large-scale use, ACORD finds the impediment to solar energy to be customer diffidence. Potential customers must accept that a solar design does not entail putting up with an unattractive living arrangement. Passive solar's estimated contribution by 2025 is 2 Mtce per year for the domestic sector.

By ACORD's definition, biofuel is non-fossil combustible material, such as dry biomass (straw, wood), wet wastes (animal slurry, food industry wastes) and energy crops (trees or plants grown specifically for energy). ACORD sees organic wastes as the main biofuels in the next 20–30 years. Research is now to be concentrated on the best conversion technologies — direct combustion, thermal processing, anaerobic digestion — for the various forms of waste. ACORD predicts a 1.6 and 8 Mtce a year contribution from wet and dry wastes respectively.

DOE also plans to continue support for geothermal hot dry rocks because of promising experimental results, even though actual output is uncertain. Research is now centred at Rosemanowes, Cornwall, in a project run by the Camborne School of Mines. The idea is to cut holes to depths of 2,000–6,000 metres, artificially fracture the rock and heat water by circulating it through these reservoirs. The project is now waiting for results from a third hole that was recently dug; if these are positive, more and deeper holes will be drilled.

Achieving technical feasibility, however, is not the final hurdle before a renewable energy project is built. These projects often have high start-up costs that are less easily dissociated from the project than are the clean-up costs of conventional energy sources. According to Mr Hunt, allowances will be made for alternative energy sources in Britain. **Elizabeth Collins**

Wind power

West Germany backs out

Hamburg

GROWIAN, (for *Grosse Windenergie Anlage*) the largest wind-driven power plant in the world, is to be dismantled. Situated on the estuary of the Elbe, it could, at least on windy days (around 300 a year), produce 3 MW of electrical power.

Developed during the oil crisis, the windmill was constructed in the early 1980s at a total cost of DM90 million (£22.5 million). Now cracks have appeared in the rotor framework which would require a further DM10 million to repair. Dr Heinz Riesenhuber (CDU), Minister for Research and Technology in the West German government, has decided instead to close the gigantic propeller down next year and to have it dismantled later. The call for the development of alternative sources of energy has become less strident now that the costs of conventional sources have stabilized, which is why the wind energy programme begun by the Social Democrat/Liberal coalition faces its end.

So far this programme has cost DM200 million, a small sum compared with the DM1,600 million invested in nuclear energy, mainly in the fast-breeder reactor plant at Kalkar. The GROWIAN project was at the outset criticized for its enormous size, and for the expected difficulty of operating such a large machine. Its cancellation is seen as a success for the nuclear lobby, which has always maintained that alternative sources of energy have no future in West Germany. **Jürgen Neffe**

French biotechnology

Making high-tech champagne

BIOTECHNOLOGY is about to be applied to those distinctively French wines and cheeses. That is the novel component of the recently approved biotechnology programme of the ministry of research and technology.

The French government and the agro-food manufacturers, France's second largest industrial community, are worried that their traditional methods are too unreliable, variable and sensitive to uncontrollable factors such as the weather to secure their place in the world markets against high-technology producers in California, South Africa and Australia. So the French food producers have decided they will use science to help.

Champagne will be one beneficiary. One of the most difficult elements of champagne technology, *rémuage*, is the removal of spent yeast from the wine after the second fermentation that produces the "fizz" and the flavour. This is already being changed by the use of "fixed", pelleted yeast. Moët-Hennessy, the producer of Moët et Chandon and many other well-known champagnes, is carefully introducing the new methods.

The company says there is no detectable effect on the flavour, and that the advantage will be that *rémuage* will take only three days, compared with the present laborious three months of slowly turning and raising the bottles until they are cork-down, followed by a swift opening and closing of the bottle by an expert to blow out the unwanted yeast. With fixed yeast, the same blowing-out is necessary, but the yeast pellets sink far more rapidly than individual yeast cells.

The saving of storage time will increase by 80 per cent the capacity of the champagne cellars that burrow throughout the champagne district, says Moët-Hennessy, which would help iron out the immense fluctuations in champagne production caused by the weather. (Champagne, one of the world's most northerly wine-growing areas, produced 300 million bottles in 1983, but only 80 million in 1981.)

The vines themselves are also under study. The small Programme Nationale de la Vigne, established three years ago by the research ministry, held its first scientific conference last spring and raised hopes that gene cloning and transfer techniques together with cell fusion and tissue culture might well produce useful new varieties. In the past, it has taken between 20 years and a century to make a new clone adapted to a particular soil and climate; this time must be shortened if new varieties resistant to disease or less sensitive to spring frosts, for example, are to be developed.

Cheese production, usually by small local makers, is also in question in a dairy industry which was shocked to hear re-

cently that Japan, which is on a wave of fashion for French cuisine, has begun to manufacture its own high-tech but tasty Camembert. This apparently uses French organisms but Australian milk, and thus represents a large market which the small French producers have almost totally lost. Scientifically, the questions again are how to achieve constancy, quality and volume.

At the ministry, the view is that after three years of government aid, biotechnology is already well established in the large French drugs, vaccines, bioreactants, fine chemicals and medical manufacturers, but that the small agrobusinesses now need a helping hand. Many of the companies are too small to have any research effort at all. Hence, according to Pierre Douzou, director of the new gov-

ernment *programme mobilisateur* for biotechnology, seven out of ten of the industrial advisers for the programme will be drawn from the agrofood industries, and the emphasis of the new programme, supported by FF 115 million (£11 million) of seed money for 1986, will be in agriculture and food.

The new trend has also been emphasized by Douzou's further appointment as chairman of the scientific council of INRA, the national agricultural research organization, which has "many fine scientists" but has been historically somewhat isolated from other French scientific communities, particularly those supported by the national and medical research councils, CNRS and INSERM, and even from the universities.

Douzou sees his job as helping INRA director Jacques Poly to "opening up" INRA to the rest of science.

Robert Walgate

European professions

Plan to make diplomas travel

Brussels

THE European Commission has drafted legislation laying down the principle of mutual recognition of all higher education diplomas throughout the Community. The aim is to facilitate the mobility of those exercising a profession. The European Commission seems to think this can be achieved without harmonization of national higher education systems. But the draft directive is very much at the beginning of a consultative process in which the European Parliament, industry, employers and various lobby groups, as well as governments, will want their say.

The measure aims at tying up a rather large loose end in Community law, whereby it is illegal to discriminate on the grounds of nationality, so that Community citizens have the right to set up their professional domicile in any of the ten countries of the European Economic Community (EEC), but where paradoxically only nationally acquired qualifications are recognized in order to be able to exercise one's profession. The only exceptions are doctors, veterinarians, dentists and architects, for whom mutual recognition of diplomas already exists.

But whereas in these cases academic curricula were to some extent harmonized throughout the Community as well, this time the Edonnino committee, mandated by heads of state at Fontainebleau in June 1984, recommended, instead, just an overall system of mutual recognition and trust, rather than the time-consuming harmonization of training courses.

The draft directive covers all professions requiring three years of higher (university-type) education which have followed a higher secondary course — *baccalaureat*, *abitur* or A-level.

It thus applies equally to paramedics

(physiotherapists, opticians, psychologists), the scientific community (engineers, geologists, agronomists), lawyers, journalists, economists, statisticians and teachers.

Information on professional recognition would be available from a computerized network linking up centres that already exist.

While the proposal is clearly an expression of political will on the part of governments towards the European ideal of complete mobility of citizens, making it easier for those whose home market is saturated to move to another EEC country, in practice it may come up against the protectionism and corporatism that characterized some of those professions.

Secondly, it is clear, as the proposal points out, that despite some measure of similarity or comparability, differences between the education and training systems in a given profession will still require the newcomer to obtain further experience or training in the proposed country of establishment. The proposal allows for a maximum period of three years but makes no budgetary provision at Community level, nor does it specify who will pay. Under Community law, a directive lays down the aims but leaves the means of achieving them to the member states. This could give rise to different financial constraints in different member states.

Achieving some level of uniformity between national education systems could further enhance the mobility aimed at by the draft legislation, but there is no provision for harmonizing education in the Rome treaties. Even if EEC education ministers do meet to discuss equal opportunities for students, this is an area in which they jealously guard their sovereignty.

Anna Lubinska

Polish universities

Doubts about concessions

POLISH universities seen at last to have won concessions from the government in their campaign against the proposed reform of the 1982 Higher Education Act. According to the leading Warsaw weekly, *Polityka*, the government Committee for Social and Political Affairs, in charge of drafting the reform, has given way on five major points. But many academics fear that these concessions are essentially cosmetic, designed to allay further, last-minute criticism of the amendments which, it is believed, will go before the Sejm (Parliament) in the near future.

According to *Polityka*, the Committee for Social and Political Affairs has decided:

- to drop proposals to replace tenure for senior lecturers and professors and to replace it by a contract system;
- to drop the proposal that rectors, pro-rectors and deans should be appointed by the Minister of Higher Education and Science instead of being elected by the universities themselves;
- to retain elections to the Main Council for Higher Education, the 70-person body representing all Polish universities and higher education schools (except the private Catholic University of Lublin);
- to allow universities to decide their own statutes instead of having to conform to a standard form of statutes dictated by the Minister;
- to retain some form of student "self-government committees", instead of replacing them by bodies linked to party youth organizations.

Although, formally, there was a major public debate on the proposed changes earlier this year, the *Polityka* article is the first open admission that the universities (as represented by the Main Council) are diametrically opposed to the government over the changes.

Moreover, *Polityka* cited several leading academics who contradict the assertion of the Minister of Science and Higher Education, Dr Benson Miskiewicz, that falling academic performance over the past three years is clear proof that the 1982 act has been used to "destabilize" the universities. The rectors of Warsaw Polytechnic University and the Jagellonian University of Kraków, in particular, are quoted as saying that while, unfortunately, there has been a decline both in the percentage of students completing their courses and in the quality of their final dissertations, there is considerable doubt as to whether this is a result of the 1982 act. This apparent "openness" of the *Polityka* article has given some encouragement to the more optimistic academics.

On the other hand, the less optimistic point out, there was never any real likelihood that tenure would be abolished.

Even a tenured lecturer can be dismissed by special decision of the Council of State (as happened recently in the case of Dr Lessek Nowak, a social scientist at the University of Poznań) and the proposal was probably included in the draft as a bargaining counter. The election of university officials will be carried out by a senate which will consist almost entirely of senior tenured staff, and without the participation of representatives of the student body and non-teaching academic employees. The abolition of elections to the Main Council is said to have been proposed, as a result of the vehement opposition shown by that body to the changes, as a means of reducing its power. Although it will not be changed into a puppet body of ministerial appointees, the Main Council still loses its decision-making powers, so that, under the reform, the minister will have only to "consult" the Main Council on terms of academic employment.

Even more serious, the minister will still retain what many see as the greatest threat of the reform, the right to dismiss or suspend any university official or lecturer, expel or suspend any student, and close down or suspend any department, without appeal or independent disciplinary hearing, if he deems it "in the public interest".

Furthermore, one should read not only *Polityka*, which still enjoys "by inertia" something of its pre-1981 reputation for a liberal outlook (by Polish standards) but also the Party daily *Trybuna Ludu*, which, only a few days previously, had given its own views of the reform. According to *Trybuna Ludu*, opposition to the reform is virtually equivalent to opposition to the Party, and, it implied, under the amended act, university employment would be dependent on an oath of loyalty to the concept of a socialist university. The idea of such an "oath" came as a surprise to most academics, who throughout the whole campaign have been largely dependent on "leaks" to the Solidarity underground press for information about what the government was planning. **Vera Rich**

British geology

Crying in the wilderness

THE saga of the declining budget for British geology took a new turn last week. In the most public and formal *cri de coeur* from the geological community so far, nine presidents and chairmen of major professional bodies* published a tract in which they summarize the present economic circumstances of their disciplines and the dire consequences they anticipate if fundamental changes, including an increased proportion of mineral taxes to be

84 amounted to 0.0043 per cent of the latter figure.

The signatories of the tract go on to outline the "impasse" with which they are confronted. In answer to the question of whether academic and institutional research is worth saving, they say, "the common government response is that if industry wants it, industry will pay for it. Industry usually replies that, as they have already paid for it in taxes and royalties, government should pay." The government's way out, say the signatories, is to tell the universities to fund research from consultancy service, an approach which, while being increasingly adopted, is bringing universities into conflict with the private sector.

The solution proposed is, in the short term, an injection of £15 million "earmarked specifically for the geological sciences... adequately to fund systematic surveys, to computerize national data-banks, to re-equip research centres of excellence and to allow UK participation in major international projects". And NERC? The document uses weasel words: "The role of NERC needs to be evaluated and the rationality of its Corporate Plan assessed" **Philip Campbell**

* Signatories: P. Allen (chairman, British National Committee for Geology), C. H. Holland (president, Geological Society), D. C. Ion (president, Institution of Geologists), W. G. Yuill (president, Institution of Mining and Mineralogy), J. Birks (president, Institute of Petroleum), P. I. Allsop (president, Institution of Mining Engineers), M. G. Audley-Charles (chairman, Committee of Heads of University Geology Departments), R. F. P. Hardman (chairman, Petroleum Exploration Society of Great Britain) and J. R. Vail (chairman, Committee of Heads of Polytechnic Geology Departments)

spent on research, are not soon made.

The decline in research commissioned by government departments, as well as cuts in funds from the Natural Environment Research Council (NERC) has led to a virtual halt in strategic surveying by the British Geological Survey (BGS) (see *Nature* 311, 499; 1984). The new document, sent to Secretary of State for Education and Science Sir Keith Joseph last week, summarizes this position but puts it in the most general economic terms. In 1983, the total mineral production (including oil) by Britain was worth £24,000 million; the tax and royalty payments from North Sea oil alone in 1984 amounted to £9,000 million. Funds from NERC for the geological sciences in 1983—

Nuclear insurance

US Congress prepares new rules

Washington

AN obscure decennial ritual that will determine who pays in the case of a nuclear accident is about to begin again. The Price-Anderson Act, which sets a limit on the financial liability of nuclear utilities, expires next year; lobbying by industry and its opponents is already shifting into high gear.

The act, first passed in 1957, was designed to remove a major obstacle to the adoption of nuclear power by electric utilities: the risk of a crippling financial burden in the event of a catastrophic nuclear accident. The act removes the right of injured parties to sue anyone but the utility, and places a limit on the liability of utilities. (The figure depends on the number of licensed reactors in the country; it is currently \$630 million.)

In its original form the act provided for the federal government to play the role of chief insurer. That provision was altered when the bill came up for renewal in 1967 and 1977 and each utility is now required to carry \$160 million in insurance; in addition, if an accident occurs that causes damage in excess of that amount, each reactor will be assessed up to \$5 million—a sort of after-the-fact insurance premium. The federal government is now liable only for accidents at its own facilities, and only up to \$500 million.

Industry, in pressing for a renewal of the act, argues that it is not a subsidy to the nuclear power industry, but rather a form of "no-fault" insurance, akin to worker's compensation. Without the liability limit, industry argues, victims of an accident might receive even less—judgements of more than a few hundred million dollars would bankrupt the average utility.

Critics point out, simply, that a major accident could easily cause damage to the extent of tens of thousands of millions of dollars; they claim that by shielding the industry from this risk, the act skews economic incentives to increase safety.

Opposition is also emerging from states that are candidates to receive federally operated depositories for high-level reactor waste, as the act limits the amount that victims of an accident at such a facility can recover to \$500 million.

Even if Congress fails to renew the act, however, the reactors already licensed would probably continue to enjoy the protection of the act. US courts have long held that legislation such as the Price-Anderson Act represents a financial contract that cannot be undone by subsequent legislation. At issue is whether new reactors coming on line after 1 August 1987 will be covered.

Several bills have already been filed in Congress:

●Simpson-McClure (S 1225) would maintain the basic framework of the act while

increasing the liability limit to \$2,000 million.

●Morrison (HR 2524) would provide for full compensation for any accident involving high-level waste.

●Hart (S 445) would repeal the liability limit while retaining the current insurance scheme; victims would be free to sue any liable party if damages exceed \$630 million.

Another alternative, endorsed by the Nuclear Regulatory Commission, would provide full compensation to victims by assessing after-the-fact premiums from all reactors at \$5 million a year for as long as it takes.

Stephen Budiansky

Genetic engineering

Rifkin set back

Washington

THE US District Court of the District of Columbia has denied the latest attempt by anti-genetic-engineering activist Jeremy Rifkin to put legal obstacles in the way of a deliberate release experiment. Judge Aubrey Robinson ruled that the National Institutes of Health (NIH) could not, as requested by Rifkin, be compelled to regulate a proposed field test of a genetically modified bacterium intended to protect crops against frost damage. The experiment, proposed by Advanced Genetic Sciences Inc., has now been submitted instead to the Environmental Protection Agency (EPA).

The experiment was recommended for approval in June 1984 by NIH's Recombinant DNA Advisory Committee (RAC), but the director of NIH withheld his approval to avoid applying different standards to private companies, as opposed to academic researchers: a previous injunction forbade NIH to approve an almost identical experiment by Stephen Lindow of the University of California until NIH prepared an environmental impact statement.

Dismayed by the legal circus surrounding the Lindow proposal and the prospect of long delays, Advanced Genetic Sciences withdrew its application (which was in any case only voluntary) and went to EPA, which has claimed legal authority over deliberate releases of some recombinant organisms.

Rifkin petitioned the court to rule RAC's original recommendation of the Advanced Genetic Sciences experiment invalid, on the basis of obscure legal technicalities; he then sought to compel NIH to forbid it.

In dismissing both petitions, Judge Robinson made plain his puzzlement with Rifkin's argument, and the experiment now lies firmly in the lap of EPA.

Tim Beardsley

Leprosy vaccine

Malawi trial to be launched

ALTHOUGH more money has yet to be found, the British Leprosy Relief Association (LEPRA) has announced the launch of a full-scale trial of a newly developed leprosy vaccine in northern Malawi in 1986 in conjunction with the government of Malawi, the London School of Hygiene and Tropical Medicine (LSHTM) and the World Health Organization (WHO).

About 15 million people suffer from leprosy, and although drug treatment is available, it can be very slow and often too late to prevent irreversible neural damage. Excitement is understandable at the development of a potential vaccine, which has been made possible largely by the collaborative efforts of a group of scientists within the WHO Special Programme for Research and Training in Tropical Diseases (TDR) coordinated by Dr Barry Bloom of Albert Einstein College of Medicine, New York.

The vaccine consists of heat-killed *Mycobacterium leprae*, the causative agent of the disease, purified from the tissues of the nine-banded armadillo, the best animal host for growing large numbers of bacteria which cannot be grown *in vitro*. Four colonies of armadillos are maintained by TDR for this purpose. Safety trials have been completed in Norway, where leprosy was eradicated as recently as 1950, and a large-scale non-random trial of 60,000 leprosy contacts is under way in Venezuela which will be completed later this year.

The Karonga district of Malawi has been chosen for the first population-wide trial largely because prevalence of the disease is rather high (1–2 per cent) and because of the groundwork laid by LEPRA's comprehensive evaluation programme in this region directed by Dr J.M. Panninghaus and coordinated by Dr P. Fine of LSHTM. Over the past six years, at a cost of approximately \$500,000, all 120,000 residents of the region have been examined and interviewed, and improved serological tests have been developed. About 1,700 leprosy cases are present and up to 240 new ones have appeared each year.

There is evidence from earlier trials that vaccination with Bacille Calmette-Guérin (BCG) against tuberculosis can provide some protection against leprosy and, indeed, animal experiments and therapeutic work in Venezuela suggest a vaccine containing both killed *M. leprae* and BCG is most promising. The aim therefore is essentially to compare this mixed vaccine with BCG alone in a randomized control trial of the whole population except those who do not wish to be involved and those who will be excluded on the grounds of age, ill-health or already diagnosed as leprosy cases.

Nigel Williams

Creationism down under

SIR—Tony Thulborn is to be congratulated on his exposure of the Creation Science Foundation in Queensland (*Nature* 9 May, p.89) and will be pleased to know that the Australian APE (Australian Association for the Protection of Evolution) is not entirely alone.

The Institute of Biology in Australia (IBA), which is a branch of the Institute of Biology and on the road to total independence, has already challenged creationists in a major symposium, "In defence of science — A response to creationism", held in Sydney with an audience of more than 200 people on 9 March. The meeting was sponsored by IBA jointly with the Linnean Society of New South Wales, the Royal Zoological Society of New South Wales and the Australian Museum Society. Speakers successfully countered persistent (and ill-informed) questioning by creationists, some of whom freely admitted to teaching creationism unofficially in science classes at all levels, in schools in New South Wales, thus confirming Thulborn's suspicions.

The proceedings were videotaped by staff from the Commonwealth (Australian) Department of Education. A short film will be released to schools soon. The papers and discussion (edited by Dr Frank Burrows) will be published by the University of New South Wales as the first volume of a new series entitled *Australian Studies in Biology*.

The fight against creationism will be continued at the second annual general meeting of the institute in Brisbane on 5–7 July. A motion will be put affirming *inter alia* that creationism is not a science and thus has no place in any biology syllabus in Australian schools.

JOHN SKIDMORE

*Institute of Biology in Australia,
Science Centre,

Sydney, NSW 2000, Australia*

SIR—Michael Cavanaugh's implications in his article "Scientific creationism and rationality" (*Nature* 16 May, p.185) cast some doubts as to whether creationism can muster sufficient support from *bona fide* academics and especially from PhDs holding established positions in reputable scientific organizations. One of the main reasons for this state of affairs, of course, is that creationists are threatened by their own colleagues and by legal action by their own school boards and institutions if they do not keep a strictly low profile either publicly or in their own class rooms. Fear of loss of respect and prestige, not to mention endangering their own jobs, is what keeps highly qualified creationists in their ivory towers (even to the extent where they avoid open association with outspoken creationists). I speak from person-

al experience and from the knowledge of what other creationists are going through.

C. K. PALLAGHY

*School of Biological Sciences,
La Trobe University,
Bundoora, Victoria, Australia*

SIR—Having reread *Genesis* for the first time in several years, prompted by Cavanaugh (*Nature* 315,185; 1985) on creationism, I still fail to see the difference between creationism and evolutionism apart from the time-scale, which could easily be resolved by postulating that one theological day corresponds to a large number of millennia, in which case we are still waiting for the events of the eighth day. If we accept this approximation, then the only difference between evolutionism and creationism is the question of the catalyst.

As the hypothesis of the creationists is a supernatural force whose existence can be established only in the after-life, it would seem reasonable to withhold judgement until after death when the hypothesis will be confirmed or refuted. Given the many millennia which modern evolutionists would consider to correspond to a single creationist's day and the relatively short time since the creation of man, which marked the end of the sixth day and which was followed by a day of rest, it would seem likely that death for most of us alive today will be an earlier event than the creationist's eighth day.

Further speculation is futile, providing creationists will concede to the evolutionists that the theological day is indeed in excess of 24 worldly hours.

Jobs in Spain

SIR—Recently, because of the large number of technical and academic professionals emigrating during the Franco years, King Juan Carlos let it be known that no Spaniard should ever again feel that he (or she) could not work in Spain. Unfortunately, the inertia of 40 years of scorning knowledge and its human heritage leaves the royal wish unheeded in the spheres which could do something about it.

During the Franco era and even afterwards, a small but steady stream of young Spaniards left Spain to do research or to benefit from higher education abroad. Many now wish to return. The national propaganda (words and wishes) wants them back; the system, however, is not willing. In Spain, positions at universities or research institutes are awarded by peculiar and primitive ritualized examinations called "oposiciones". In principle (and on paper) they are open to any Spa-

niard. The reality is different; only Spaniards with a Spanish degree can apply. In short, a degree of any kind from a foreign university (regardless of its name or place) is not valid and the knowledge that accompanies it is questioned. Of course, the bureaucracy provides a simple way out: "convalidacion" (validation). One can apply to validate one's degree; what this involves varies and, in general, is inversely proportional to how many influential personalities the applicant knows.

It is a sad and deplorable situation, particularly in the euphoria of Spanish integration in Europe. The absurdity of the situation is clear from the fact that any Spaniard with a Spanish PhD can obtain a job in Europe or the United States, without any bureaucracy or any more questions than those related to the job; any Spaniard with a PhD, from, say a US, English or German university has to fall into a "windmill battle" with Spanish academic authorities and thus is not eligible for a job in his/her own country.

It is important that these ancestral prejudices disappear. They are probably a consequence of the isolationism that has characterized the Iberian peninsula for centuries. The accession of Spain to the European Community attempts to break the barriers that extend above the Pyrenees. Let us hope that it breaks all barriers. ALFONSO MARTINEZ-ARIAS

Hills Road, Cambridge CB2 2QH, UK.*

Scientist arrested

SIR — We have heard from scientists in Poland that their colleague, Zbigniew Gluza, has been arrested. Gluza, aged 33, was employed at the editorial board of the journal *Informatics*—the leading publication in the field in Poland—and is a member of the Polish Informatical Society. He was also a member of Solidarity.

Zbigniew Gluza has become a victim of the regime and an example of the planned programme of repression being suffered by Polish intellectuals.

During a random inspection in the street in Warsaw, the Polish *milicja* found some popular underground literature in Gluza's car. It should be pointed out that these underground bulletins play an important role in Poland, because official publications do not carry a genuine news digest—only officially edited reports which are usually distorted by ideology and its powerful instrument, censorship.

Letters of protest are being written to Polish embassies, consulates, cultural and scientific institutions. It is to be hoped that international groups and societies will add their weight to the protest. The efforts of private individuals will also be welcomed.

CONVENIENT-INFORMATIVE-TIMELY-PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1 ■ You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2 ■ You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information...the latest instrumentation...marketing breakthroughs...funding sources...new technologies...patents and licences...profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3 ■ You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4 ■ You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

New Zealand's Leading Publisher of Science and Technology

SCIENCE INFORMATION PUBLISHING CENTRE

Science Information Publishing Centre (SIPC) is the centralised publishing house for New Zealand's Department of Scientific and Industrial Research (DSIR). SIPC's main objective is to bring to New Zealand and the world the results of New Zealand research that advance knowledge and the application of this knowledge as technology.

DSIR is the largest scientific organisation in New Zealand, maintaining a wide-ranging programme of research and development and services across the major scientific and technological disciplines.

SIPC's publications reflect both DSIR activities and, through the New Zealand research journals, the research carried out by the New Zealand scientific community and its institutions. Often the authors are addressing an international readership, vitally interested in the environmental uniqueness of New Zealand and its neighbours—from the tropical Pacific islands to the Antarctic continent.

SIPC's role is to publish and disseminate both professional knowledge and popularised science and technology through quality publications ranging from journals and booklets to films and videos. Increasingly, SIPC's books are being aimed at international markets.

For Research Scientists

SIPC publishes the *New Zealand Journal of Agricultural Research*, *Botany*, *Experimental Agriculture*, *Geology and Geophysics*, *Marine and Freshwater Research*, *Technology*, and *Zoology* as independent primary journals to disseminate the results of research carried out largely by the New Zealand scientific community. *New Zealand Science*

Abstracts records abstracts of New Zealand's published and unpublished scientific literature.

A wide range of international scientific monographs is published in the general *DSIR Bulletin* series; in specialised series on regional geology, paleontology, and oceanography, and in taxonomic volumes such as the *Flora of New Zealand* and the *Fauna of New Zealand*.

For Other Groups

SIPC is increasing its diversity of publications, especially those relevant to industry, both general and biologically-oriented. It publishes the *DSIR Industrial Information Series* and leaflets for extension workers and industrial users, *DSIR Discussion Papers* and the *DSIR Social Science Series* for decision and policy makers; and the *DSIR Information Series* and other printed material for secondary and tertiary students and the general reader.

In addition, SIPC sells DSIR *film and video presentations* largely aimed at specialist groups of scientists or groups within the biological and manufacturing industries.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Science at a very great distance

Australia and New Zealand are in a different part of the world from most other places, as the cover shows. They are also a long way from each other, geographically and in other ways. This survey of science in the two countries is necessarily far from complete. It is offered as evidence of the vitality and promise of what is happening in these interesting places.

Australia's technical revolution

THE government of Australia is in danger of talking itself into a muddle about science and technology. Australia is blessed not only with great natural resources and a splendid climate but with a superb scientific enterprise. The government has rightly diagnosed the economic decline of the past few years as the consequence of Australia's failure to increase exports of manufactured goods to compensate for the diminished value of exports of primary materials, agricultural produce and minerals, itself a consequence both of the world-wide recession and, in agriculture, of protectionism (as by the European Communities). For this reason but also by the inspiration of Mr Barry Jones, the Minister for Science, Mr Bob Hawke's Labor government has been, during its two years in office, embarked on a great drive to turn Australia into a technological community. It is a brave and laudable ambition, which should have enlivened the technical community. Why, then, are the people who work in academic and research laboratories more anxious, even despondent, than they have been for many years?

A large part of the trouble is that the technical community, while sharing the government's aspirations that technology should be made economically more valuable, fears that the government will not put its money where its mouth is and that its enthusiasm will get the better of its judgement. Last year's failure in the budget process to make a substantial increase in the funds of the meagrely supported research grants scheme for academics is worrying, as is the requirement that the public research organization (CSIRO) should do more (industrial innovation, especially) with less. And there is little sign that the Hawke government's conviction that the supply of skilled people from Australian universities must be increased will be followed by commensurate support. Will the government show that it means what it says in next month's budget?

Exorcising anxiety of the second kind will be more difficult. The prophet of the revolution the government hopes to work, Mr Barry Jones, is politically more radical than pragmatic Hawke, but he properly

appreciates that basic science is as crucial a part of technological change as is the engineering of innovation. The practitioners of the revolution are harder men who share Jones's vision and impatience but not his understanding. Collectively, they give the impression that scientists who are not working for industry are a bunch of layabouts. The obvious danger is that they will intemperately enforce changes that damage Australian science without yielding much in the way of economic benefit. Aesop's fable about the dog, and the reflection of his bone in the water, applies.

The torrent of public introspection since 1983 about the engineering of Australia's revolution has been more confusing than clarifying. This month's second draft of the "National Technology Plan" (from which Mr Jones mildly dissents) is even fuller than last year's version of specific goals, and actions to be taken by government and others. Even in a country as used to being overgoverned as Australia, the proposals seem over-dirigiste; is it possible, let alone desirable, that part of the government's subsidy of universities should be "earmarked" for "mission-oriented basic and applied research" intended to make existing industries more competitive and to create entirely novel industries? That is what the plan says.

A more serious weakness of the public argument about the future is that it seems innocent of serious consideration of what Australia might be like economically if and when the revolution has come to pass. Australia seems ready to turn its back on the traditional sources of its wealth. In the dash for a new prosperity, and with the knowledge of what the foreign exchanges have been saying this past year about the dangers of over-spending, the government's motto seems to be: "If people don't want our beef, we'll do research on something else". And so, inevitably, there is a new strategy for research, with priority objectives clearly spelled out: biotechnology, information, robotics and the application of computer-aided design to manufacturing technology and materials. Australia, with its 15 million people, is bursting to follow every European country in attempting to simulate what has been happening in the United States and

Kiwi alert

NEW Zealand's scientists face hard times. The government has decided progressively to lower the budgets of the major research organizations over the next three fiscal years. There will be further cuts in real funds, particularly in the universities, as inflation, now running at 15 per cent, makes itself felt. For the government, the falling budgets are regarded not so much as "cuts" as incentives for the recovery of funds from elsewhere. The gap that opens up as grants are reduced is meant to be filled by increasing the amount of money taken in from industry and from other government departments by contracts and by the sale of services. In a nutshell, "the user must pay for science".

In as far as they are to suffer financial austerities, scientists find themselves in much the same boat as many others in New Zealand. Despite its celebrated anti-nuclear stand, the new Labour government has brought in tough monetarist policies. It inherited a massive deficit from the outgoing National Party government and decided that a sharp shock was needed to wake New Zealand to the harsh economic realities. The first action of the new Prime Minister, David Lange, after winning the election last year was to devalue the dollar by twenty per cent; subsequently, it was allowed to float and its value has fallen further. Import licensing systems which had long protected local manufacturers were done away with, along with controls on financial markets. Some farm subsidies were also thrown out. Next, there is to be radical overhaul of the tax system aimed at slashing personal taxes and passing the bill to goods and services.

It is not hard to see why Lange decided on drastic action. In the mid-1950s, the country was the third richest in the world measured by per capita income. Now it is close to twentieth. The cause of the decline can be summed up in a sentence: the balance between primary and secondary industries is not appropriate to keep a small country in prosperity. In New Zealand, primary industry means agricultural products, principally meat, wool and dairy, making up 80 per cent of its exports. Markets for them are becoming harder to find and more and more unstable.

The solution to the problem is, in one

AUSTRALIA and New Zealand, until recently among the most prosperous countries in the world, have fallen on hard times. In each case, the explanation is that world demand for primary products has fallen. Each country has responded by setting its sights on the exploitation of science and technology to make products that will find new markets. For what it is worth, both countries have also within the past two years elected governments from the left of their political spectra, Mr David Lange's Labour government in New Zealand and Mr Bob Hawke's Labor government in Australia. (The word "programme" is also spelt with a single "m" in Australia.)

This survey of science in both countries is necessarily incomplete. *Nature* wishes to thank the many scientists and politicians in both countries for their helpful courtesy and also Dr Jeffrey Sellar, *Nature's* Canberra correspondent, and his predecessor, Dr Vimala Sarma.

NOTE: \$A1 = £0.51; \$NZ1 = £0.35

Japan Nobody seems to have thought much about the possibility that when demand for the traditional products is depressed may be the worst time to rob them of research support.

Yet what is wrong with Australian industry is not that Australians are unenterprising, or that Australian scientists are unimaginative or even that Australian workers are lazy — these are the opposites of the truth — but that Australia created for itself in the comfortable 1960s and 1970s an unreal economic framework whose abandonment not even the most radical politicians can advocate (in public). Australia has indulged xenophobic instincts about capital investment (wholly-owned subsidiaries of overseas companies are bad) and chauvinistic instincts about overseas trade (high-cost local manufactures behind tariff barriers are preferable to cheap imports). The result is that Australian manufacturing industry is inward-looking, persuaded that its only worthwhile market is Australia. So it is no surprise that Australian imports of technologically-based products are worth eight times the corresponding exports, or that the volume of research carried out by Australian companies is tiny (For Australian companies, the domestic market is not big enough to support full-blooded research; overseas companies do their research at home, although ICI and Kodak are exceptions.) Yet Australia's determination to become a technological economy has been prompted by the recent discovery of this unsurprising state of affairs.

This is why Australia could best satisfy its ambition to become a technological community by liberalizing the framework which has so far held it back. Mr Hawke and his Treasurer, Mr Paul Keating, have spent the past few weeks battling for a radical reform of domestic taxation

(which is a good cause, but one in which they will only partially succeed). To make their technical revolution happen, they must also reform the external economic relations of Australia. Devices such as the 150 per cent tax allowance (see p.189) will no doubt help, but can be no more an assurance of success than is the palliation of symptoms a cure for a disease.

What the government must appreciate is that, with 15 million people, it cannot be (and does not need to be) a powerful source of innovation and production across the whole field which it now wishes to explore. Indeed, Australia would be on safer ground if it were to build more energetically on the strengths it has already. The application of biotechnology in agriculture (animals as well as plants) is full of a promise that has been recognized. The reasons why Australia ships metal ores and the coal with which to reduce them to countries overseas (Japan particularly) is a puzzle, but one in economics Australia's apparently perverse determination not to add economic value to the uranium it sells abroad is political in origin, but a costly self-encumbrance. Australia's medicine has and deserves the highest reputation internationally, where are the pharmaceutical industries that would have sprung up elsewhere?

The risk in the indiscriminating course the government seems bent on following is that the quality of the present scientific enterprise will be undermined. That is what alarms many academic scientists. A modern state such as Australia needs to be in touch with what is happening in the whole field of science (which is why there should be no shame that many CSIRO laboratories are able to hold a watching brief on what may be happening elsewhere). There is no harm in offering people incentives to see their bright ideas turned into saleable products, although it is absurd that there should be such pressure from the government to ensure that Australian innovations are exploited only by Australian companies. But to expect that every working scientist should contribute directly to the revolution is a recipe for disaster.

The government's greatest need is for patience. It is right to look for a technological revolution in Australia, but not to expect this to happen overnight. It does not much help that it has chosen this time to review the operation of pretty well every important organization spending money on science. Might not some of them be allowed to get on with what they do already? (CSIRO, the largest public research organization, is in a different case; its management structure is not appropriate for the functions now expected of it; see p.189). Although part of the trouble is the short interval between elections (never more than three years), the government must learn to recognize the excellence of the science enterprise it has inherited and learn to meddle less. □

sense, obvious. First, value must be added to New Zealand exports: more pulp and paper and less timber, more carpets and less wool. Second, the range of products must be increased; new types of cheese must be developed, new fruits grown, and meat processed in new ways for new markets. And third, more manufactured goods must be developed in areas where New Zealand is "believable"; farm equipment, software packages for farm management, portable communications equipment and the like.

How to bring about these changes is less than obvious. Lange's policies have so far proved a major shock to the economy. Growth has fallen to less than one per cent this year compared with four per cent last year. But in a phrase that will be familiar at least in Britain, Lange says that New Zealand cannot continue to "live beyond its means".

The bludgeon that has been applied to the economy is now to be applied to science. The government may yet regret what it is doing. New Zealand's problem in research is that there is a great deal of talent, of which a large part lacks the means to show what it is capable of.

The imaginative technological changes needed in the economy require that talent be put to use. But simply trying to harness science to industry through contract work is unlikely to be productive, for industry does not have a clear enough idea of its own long-term interests to be able to direct research sensibly. Nor does it understand that without basic research before long there will be no applied research worthy of the name. The government pays lip service to the idea that science must be promoted. It seems not to see the danger in reducing budgets indiscriminately.

There may be an explanation. All the signs are that the government is remarkably ignorant of science and technology and generally holds scientists, as against managers, in low regard. Occasionally one hears that the "Japanese way" should be followed; and that all science should be put in the service of industry. But that is not the real situation in Japan. If anything distinguishes that country, it is the premium placed on being well-informed about scientific matters: the Prime Minister heads the key scientific policy-making body and there are reams of reports and statistics. In contrast, it was only a few months ago that anyone in New Zealand had more than a half-accurate idea of how much industry was spending on research. What the government should be doing is finding out what the nation's scientists — and the universities constitute a major pool of under-used expertise — can contribute. And that identifies what seems to be a major weakness of the present administrative system. No powerful voice represents science to a high level of government. But without giving science high priority, how can the technological change on which New Zealand has set its mark ever be achieved? □

How science is run in Australia...

Most government ministries spend some money on research. (Defence is excluded from the diagram above.) The numbers attached to each ministry are the estimated expenditures in 1984-85 on research and development in millions of Australian dollars. The particular complication of Au-

stralia is that the federal structure shown above is paralleled by a comparable pattern of administration at the state level; especially in agriculture, states are substantial spenders on their own account (while research funds are also recruited by means of a levy on certain products).

... and New Zealand

As well as those shown above, two other ministries have research arms: Transport (New Zealand Meteorological Service), and Works and Development (Water and Soil Research and Survey group). Grants

are also provided by the Medical Research Council to universities, hospitals and its own small research units for dental research, virus toxicology, immunopathy and alcohol research.

Science and technology

FUNDING for New Zealand's research and development for the year 1984-85. Government spending is \$NZ150 million, the universities \$NZ200 million and industry \$NZ69 million. Had the chart been drawn a little earlier it would have been divided into quite different slices, for it has only just been discovered that industry spends a considerable sum on research. There is a simple reason for that: because expenditures on research for new products (as against current product lines) are not tax-deductible, research costs have consistently been hidden under "maintenance costs" and other such categories. A new survey has revealed the above figures and in doing so destroyed a recent OECD analysis which centred on the belief that industrial research and developed effort was tiny.

THE Department of Scientific and Industrial Research (DSIR) takes the major share of the government funds.

Texture of diversity in Australian science

THAT Australian science is in good shape needs only the most cursory inspection. Traditionally, agriculture is the country's strong suit; growing crops in arid regions is one of the exportable technologies developed, veterinary medicine another. Since 1945, biomedical research has flourished, largely at the urging of Lord Florey and Sir Macfarlane Burnet. So too has astronomy, partly because of Australia's geographical position in the Southern Hemisphere.

What follows is a kaleidoscope of impressions gathered on a rushed journey during June. By being selective, it is necessarily unfair except in the sense that the random citation of a few high-quality projects may prove that there is much more of the same unmentioned.

Australia is strong in the application of *in vitro* fertilization to childbirth. Dr Carl Wood, professor of obstetrics and

gynaecology at Monash University, and Dr Alan Trounson, direct one of the centres. Wood says that his work is a natural extension of veterinary developments in Australia. He reckons that throughout Australia, there are 10,000 women waiting for treatment, more than 2,000 at his own clinic.

Melbourne is a medical powerhouse, with two important medical schools and a traditional backing of outstanding public hospitals. The university has also become one of the several centres of biotechnology in Australia, since when its botany department has been singled out as a centre of excellence by the Tertiary Education Commission. Dr Adrienne Clarke, head of the centre, says she decided deliberately to spend half of her \$A2 million grant on mass spectrometry equipment. Partly as a consequence, her laboratory has become even more the hub of collaboration on the

molecular basis of plant cell physiology.

Throughout Australia, specialized institutes such as the Hall and John Curtin institutes and university departments are turning as quickly as they can to molecular biology. So is CSIRO, partly on the strength of a report by a committee under Dr N.K. Boardman in 1979.

CSIRO's Division of Molecular Biology in the North Ryde suburb of Sydney is one of the smaller divisions, with a professional staff of 48, roughly one-third of them paid for by contracts with outside organizations. How does such a laboratory cover the ground?

Dr G.W. Grigg, the division chief, is a little alarmed that too many of his bright people will devote themselves exclusively to practical projects, making the laboratory less effective at its indispensable role as an impartial source of advice for Australian industry at large. In practice, the

laboratory has already helped to spawn a substantial company, BIOCLONE, an international supplier of monoclonal antibodies specific for pituitary hormones.

Sydney houses a clutch of important CSIRO divisions, including that for mineral physics which claims to have pioneered remote sensing in Australia. Among other things, the division is using magnetotelluric techniques for mapping oil reservoirs, and claims the first systematic application of palaeomagnetism to the study of ore bodies. But its practical product is an instrument called SIROASH which uses nucleonic techniques to measure the bulk ash content of coal; the underlying phenomena are gamma-ray scattering and electron-pair production.

Sydney is also one of the centres of Australian astronomy, largely because of the long collaboration between the department of physics at the university and the CSIRO Division of Radiophysics. Sydney physicists are the prime movers in the plan to build the Australia Telescope, a \$A25 million radio interferometer consisting of an array of six 25-m dishes strung out along a track 6 km long.

This ambitious project is the responsibility of the CSIRO Division of Radiophysics, which believes it will be able to engineer an instrument whose frequency coverage, accuracy and sensitivity will be without precedent. The radiophysics division hopes that its expertise in the design of antennae feeds will contribute to the success of the equipment.

Optical astronomy is also prominent, the flatness of the ancient continent of Australia notwithstanding. The Mt Stromlo Observatory (40 minutes from Canberra), part of the research school of physics at ANU, claims to be the one of the most influential sources of professional astronomers in the world. Its facilities are remarkable, but mostly to be found 500 km to the north, at Siding Spring, which is also the site of the Anglo-Australian telescope.

The latest acquisition is a home-designed 2.3m telescope built at a cost of \$A3.2 million and opened in March 1984. Dr Don Mathewson, director of Mt Stromlo, is especially proud of three features of the project — the fact that the six-inch thick mirror blank (thin as these things go) was fashioned by sawing a Corning blank in half laterally, the altazimuth mounting of the telescope and the fact that the building in which it is housed rotates as a whole on its axis.

The Anglo-Australian Telescope is similar kettle of fish. Dr Dan Morton, the director, reckons that Australian astronomers profit more than British from the facility. As of last month, nobody at the office had been informed officially of the decision by the British Science and Engineering Research Council that continued support (£1 million a year by each side) did not come high on the research council's list of priorities. People in Sydney

say that the agreement to operate the telescope is embodied in a formal bilateral treaty between the governments concerned, and that it cannot be abrogated by the agent of one of them. The next few months should be interesting.

Australia's interest in astronomy has also in the past few years been furthered by the plan, now aborted, for a tripartite collaboration (with the United States and Canada) to operate a 1-m reusable telescope package from a low orbit about the Earth. In Canberra, they have no doubt that the system would have been more economical than the Hubble Telescope.

So Mt Stromlo is now hoping that something will come of another plan, involving both the US National Aeronautics and Space Administration and the European

Space Agency to launch a far ultraviolet detector as part of the Fuse/Columbus project.

This is the conventional part of the exploration of the world outside the Solar System; the radical part is the experiment, based on the physics department at the University of Sydney, by means of which an attempt is being made to put flesh on the bones of a proposal due to Professor R. Hanbury Brown to build large-scale Michelson interferometers from which to extract the diameters of distant stars and galaxies. The department is now bringing into commission an interferometer with a baseline of 11.4 m. Then it will set out to raise more than \$A2 million. Either way, like much else that happens in Australia, the instrument will be unique. □

ASTEC

Vehicle for wise council

THE most remarkable component of the Australian government's machinery for the administration of science and technology is the Australian Science and Technology Council (ASTEC), a device by which independent scientists not only give advice when asked but have a kind of prescriptive right to comment on government policies with technical implications. The closest analogue of ASTEC is historical — the US President's Science Advisory Council (PSAC) in its heyday of the 1950s. PSAC, alas, had lost much of its influence by the time it was abolished in 1971; ASTEC, on the other hand, was invented less than a decade ago and was given a statutory place in the machinery.

ASTEC is not a substitute for a Minister for Science; there is one of those, Mr Barry Jones. Nor is it the minister's creature; rather, it reports directly to the Prime Minister, now Mr Bob Hawke. The council itself, now eighteen strong, is a roughly equal mixture of academics and users, mostly from industry. The chairman is, Professor R. O. Slatyer, director of the School of Biological Sciences at the Australian National University.

Unlike science advisory committees elsewhere, ASTEC is adequately staffed. The secretary, Dr B.D. Middleton, emphasizes that ASTEC's distinctive role is its oversight of the whole of government business (for which reason the organization has access to cabinet papers). Often, he says, ASTEC has persuaded the government that a proposal given only low priority by a minister should be given more serious attention. ASTEC claims some responsibility for the decision a few years ago to re-equip the Bureau of Meteorology and to contribute to the international seismic network for the surveillance of nuclear explosions.

An important part of the philosophy of ASTEC is that its members work hard (they are now paid \$A11,000 a year). Last month, they were collectively finishing off

a round of visits to all the 40 divisions of CSIRO as part of a major enquiry into the role of research in Australia.

By definition, ASTEC cannot avoid being part of the political process. So much is clear from the review of Australian uranium policy, published a year ago (see p.200). One explicit objective of the inquiry was to consider the adequacy of safeguards on the export of uranium.

It seems not to have damaged ASTEC's standing that the government was unable to accept the key recommendation that Australia should play a fuller part in the fuel cycle than as a uranium supplier.

ASTEC seems also to be capable of political initiatives. The government's announcement (in May) that from the beginning of the next financial year (1 April 1986), expenditure on research and development by private companies will qualify to the tune of 150 per cent as a business expense had its origins in ASTEC's glooming about the low level of expenditure by Australian companies.

The present inquiry about the function of research in Australia is a different kind of nettle. The Hawke government's determination that almost every public institution should be reassessed suggests that the question would inevitably have had to be grasped at some stage. That CSIRO should be singled out for the first and most contentious chapter of this crucial examination suggests either that ASTEC has woefully accepted terms of reference that prejudge the outcome, or that ASTEC has preconceived ideas about the location of buried bodies. The best guess is that the truth is neither extreme.

None of this is a complaint. In the past year or so, ASTEC has tackled subjects as different as the place of Videotex in Australia and technology's role for the handicapped. Part of the reason for its influence is that it will deliver what ministers (of whatever party) need. Now and again, it may be able to stir the pot. □

Government's role

Minister with his own vision

In a system of parliamentary government, in which the officers of the executive are chosen from among the people's representatives, every government needs one minister like Australia's Minister for Science, Mr Barry Jones. Whether it could live with two like him is another matter.

Mr Jones, less of a minister than a prophet with political pretensions, is known to both those who have never met him and his enemies (who abound) as "Barry". Barry, in the argot, rendered Prime Minister Bob Hawke a signal service before and after the election of March 1983. Single-handedly, he has made science and technology into an issue that ordinary people take seriously. Nowhere else, except possibly in India now and the Soviet Union in the 1930s, has the exploitation of science and technology been as proper a subject of polite conversation as it has become in Australia.

Mr Jones first became a national figure as an astonishingly successful competitor in the television quiz shows of the 1960s. People still tell of the occasion when he proved that the television network and not he had given the wrong answer. Long memories, of course, do not necessarily make for congenial politics.

Mr Jones has a sense of duty and is considered to be on the left-wing of the Labor Party. He is the author of *Sleepers Wake!*, a tract which, in 1983, sought to persuade Australia that it must use and live with technology if it is to hold its own.

Mr Jones has kept talking about the need for change consistently since taking office in March 1983. In the process, he has popularized the problem of technological change and also helped to confirm his own popularity. But there have been two substantial set-backs. The first, just a year ago, was a shock to those of Mr Jones's supporters who may have thought he was about to wave a magic wand; in the event, the funds for providing university research grants (see p. 194) did not increase by the promised 10 per cent but only by the amount of inflation.

Explanations of what went wrong differ. Some say that the minister brought the trouble on himself by putting increased science spending a long way down his list of priorities, certainly after his proposal for the Commission for the Future (not another exercise in futurology but an attempt to increase Australia's capacity for change). Some think he was playing a devious game by counting on the government's commitment to ensure that the increase came through. The most likely explanation, however, is that the meagreness of the increase may have been a reprisal for Mr Jones having fought within the Labor caucus for complete withdrawal from the uranium mining industry.

Mr Jones's second setback came only after the general election last December, when the Hawke government was returned with a reduced majority. The technology part of the science and technology portfolio was whipped away, and handed to Senator John Button, previously at the industry and commerce ministry, one of the government's strong men and (unlike

CSIRO's industrial might

INDUSTRY has always been an important component of CSIRO's terms of reference. The novelty is Australia's new-found conviction that it can no longer rely on agriculture and minerals to balance the cost of the products its people must import. CSIRO seems eager to play its part.

So the organization now has a fully-owned commercial subsidiary to help with the exploitation of innovations arising in the divisions and called SIROTECH. (SIRO is CSIRO's way of referring to its role as originator in projects as different as SIRONET, a computer network, and SIROSMELT, a small-scale but efficient way of extracting base metals from ores.)

After only 18 months, it is too soon to know how effective the new company will be. Its terms of reference allow it to become the manager of intellectual property, patents and the like, arising from research at the divisions. The company can also invest in "pre-development" work.

Meanwhile, division chiefs seem still to have much of the responsibility for the exploitation of their people's work. Dr G.W. Grigg at the molecular biology division at Sydney reckons to have been the one who

Mr Jones) also a member of the Cabinet.

The reasons for the change seem to have been administrative rather than political. Just as he is not cast in the standard ministerial mould, so he is by everybody's consent except his own a poor administrator. Priorities change too often: he creates a sense of rush when civil servants prefer serenity. Serenity is not Mr Jones strong suit. Much of his personal popularity stems directly from his open friendliness. He is almost too open to be a successful politician, and in any case, he is too imaginative. □

persuaded a Sydney businessman to invest in the production and marketing of a range of monoclonal antibodies. Dr J.R. Anderson at the materials science division at Melbourne worries on a day-to-day basis about the zirconia ceramics project.

Except in agriculture and minerals, Australia has traditionally been a protectionist economy. One consequence is that the Australian manufacturing sector is neither export-conscious nor compelled, by the international market, to be as conscious as would be wise of quality.

So innovators are faced with a dilemma: should they license their bright new idea to an Australian company, knowing that they can help guide the development of the product through the critical stages and earn a substantial royalty on sales at the end, or should they sell the licence to some company overseas, earning a smaller percentage on what may be a larger volume of sales?

Hitherto, political considerations (not to mention the character of CSIRO) have forced local licensing policies on the organization. Will SIROTECH break this pattern? □

CSIRO

Time for thinking again

FOR much of the period since the Second World War, the name for Australian science has been CSIRO, short for Commonwealth Scientific and Industrial Research Organization. During most of that time, the organization has ridden high, rightly boasting of its splendid achievements in agricultural research, innovative work in basic research and of being the chief custodian of Australia's international reputation in research.

But now the gilt is flaking off the gingerbread. The universities are stronger than they used to be, while government is increasingly concerned to know what benefits it gets for all the money (\$A382 million in 1983) and the services of all those people (more than 7,000 staff, over 2,000 of them professionals). So CSIRO is on the defensive. ASTEC (see p.188) has been asked to inquire into the entire role of the research enterprise in Australia, but to give priority to its views on

CSIRO, which is conscious of having blotted its copybook with the new government and which is responding a little frenetically to the clamour that research should benefit manufacturing industry.

Some in the government do not forgive CSIRO for the letter sent by its chairman Dr Paul Wild to the incoming government asking that the organization should be transferred from the Department of Science and Technology; the letter went off before the cabinet had been sworn in, and so was delivered to the out-going Fraser government, irritating both camps.

But even those with the shortest memories recall the great row over the Australian National Animal Health Laboratory at Geelong, near Melbourne, partly because of the high cost (\$A157 million) but mostly because the plan to import live foot-and-mouth disease virus had not been discussed with a quarantine-conscious agricultural community.

Farmyard computers and biotechnology

At the CSIRO Division of Plant Industry it is clearly passé to ask what impact molecular biology is having on agriculture. People have stopped thinking of it as a subject; it is rather a set of tools which everyone uses.

There is no doubt that the division is a dynamic one and that it has a dynamic boss in its director Jim Peacock. One suspects that a man who became director of a plant industry laboratory by working on *Drosophila* will have no difficulty in persuading government of the value of whatever he feels should be done.

Balance between basic research, "strategic mission-oriented research" and short-term applied research is maintained at 20:20:60 per cent. But there is clearly a premium placed on generating new concepts for agriculture from basic research (such as the developments of diagnostic kits for plant viruses) rather than just "agricultural improvement".

It is not only molecular biology that is taken for granted in the division; computers have also arrived. One hundred million dollars worth of the annual cotton crop is now grown to a tune sung by a computer-

based management system, SIRATAC.

In the SIRATAC system, years of data collected on crop growth, insect pests and insecticide effectiveness are built in. Every few years the farmer inputs on his own terminal the numbers of insects on his cotton and the numbers of fruit; the central computer adds weather data. The program then predicts from the likely effects of weather, beneficial insects and previous sprayings the mortality of fruit and the number likely to survive to harvest. This is not so simple as more fruit are produced than will mature; light insect damage might even increase yields by removing unnecessary fruit.

Beyond SIRATAC come systems for other types of irrigated agriculture. SIRACROP is now poised for commercial development and will decide irrigation schedules for farmers growing wheat. And beyond that again comes a total system for a range of crops — soybean, maize and the like — which will not only increase farmers' profits but also stop the poorly managed use of water contributing to rising water tables.

Alun Anderson

One casualty of this distrust seems to be Dr Wild, the chairman, whose term of office ends in September, and who will be replaced for nine months by Dr Keith Boardman, formally due to retire as a full-time member of the executive of CSIRO on the same date. Dr Wild, previously director of the Division of Radiophysics at Sydney, and the driving force behind the distinctive Australian system for landing aircraft automatically, is generally thought to have been poorly equipped with the mixture of guile and directness required for success in Canberra. CSIRO is unusual among the descendants of the organizations set up in the 1920s in what the British call the old Commonwealth. Its terms of reference cover everything from agriculture to minerals extraction and metal processing to general support for manufacturing industry. Two years ago, CSIRO adopted a self-denying ordinance on medical research, agreeing that it would not undertake clinical research except in collaborations.

CSIRO's structure is as unusual as its scope is unbounded. The chief executive is the chairman, appointed by Canberra, who has two full-time fellow members of what is called the executive, on which day-to-day decisions fall. There are also five part-time members, whose function seems to resemble that of the non-executive members of corporate boards — to act as informed referees. Key decisions rest with this handful of people. There is also an advisory council whose function is not so much to participate in decisions as to interject opinions.

Part of the more obvious trouble is that this band of men, housed in a new piece of modern concrete half-way to the airport at

Canberra, is necessarily a long way from where research is practised. Day-to-day matters take precedence: thinking ahead is harder. The remoteness of the executive has been enhanced by an earlier reorganization, in 1972, when individual laboratories (called divisions or sometimes units) were grouped into five bundles, called institutes, each with a director of its own. These, too, appear to be condemned to too great a burden of paper-pushing. The real directors of research are the heads of the divisions (of which there are 44), known as "chiefs" and addressed by their colleagues by that word. Typically, a chief will be a man in his fifties, often one with scientific distinction overseas, but who will usually volunteer that his chief function is to provide an environment in which younger people can be creative.

Scale is more difficult. Typically, a division will have about 50 working scientists, formed into perhaps half a dozen research groups. Some division chiefs admit that their laboratories are big enough only to make a few distinctive contributions to the international enterprise so as to earn the right to keep a watching brief on what is happening elsewhere.

The quality of the work seems nevertheless to be uniformly excellent. So why do Australian governments not cherish CSIRO as in the old days? Part of the explanation is that there has been a change of government. Although discontent has been rumbling for many years (witness the 1972 reorganization), and while the Hawke Labor administration is in no sense a doctrinaire socialist government, it was elected partly on the strength of Mr Barry Jones's plea that Australia should prepare to join the twenty-first

century (see p.188); it was natural that CSIRO should have felt threatened by its arrival.

Some of the accusations made against CSIRO are nevertheless unfair. Thus it is widely held that the organization is not, or not sufficiently, accountable. Unlike many other research organizations, however, CSIRO is not autonomous. Quite apart from the familiar mechanism of control by annual budget, CSIRO's enabling act (of 1949) gives the government the right to issue directions to CSIRO. Internally, CSIRO operates a system of periodic reviews of its divisions, the consequences of which are often the amalgamation or reorganization of laboratories, or substantial changes of the emphasis. If accountability at the bench means a sense of people looking over one's shoulder, CSIRO is blameless.

CSIRO is, however, vulnerable to the complaint that it is ingrown. Unusually, it is a career research organization. During the past quarter of a century the supply of home-grown research scientists has grown from a trickle to near-sufficiency. CSIRO has become a substantial source of academic and industrial scientists, but its core staff has become over-used to what many think of as the traditions of the service. Bringing in people from outside, especially to senior posts, could not fail to help.

CSIRO's research effort by purpose and/or beneficiary, 1983-84. Numbers indicate professional scientists engaged. Source: CSIRO Annual Report.

CSIRO is also large, in Australia, conspicuously so. The central administration of close on 50 establishments and the wise arrangement of objectives in some coherent order would tax the most enlightened organization. The concentration of responsibility on the shoulders of three full-time executives seems to predetermine both the appearance of stubbornness and that of irresolute compliance to outside pressure.

The terms of reference are in some ways an encumbrance: "... to plan and carry out a comprehensive program of research on behalf of the Commonwealth for the benefit of the people and industry of Australia". Research policy is thus not easily distinguished from public fashion.

The present policy (see *Annual Report, 1983/84*) is to transfer to seven fields (biotechnology, advanced materials, manufacturing technologies, information technology, water and soils, plant pathology

and oceanography resources that can be quarried from elsewhere by natural wastage (3.5 per cent a year).

The recent growth of numbers of those working in these fields is impressive evidence of how a determined executive can make things happen; the danger is that the interest of continuing research in both minerals processing and, more particularly, agriculture, will be undervalued. The importance attached to biotechnology may have agricultural implications, but there seems to have been only scant consideration of the continuing need for research in agriculture, or even that when markets turn sour, the need for research may be all the greater.

The other side of this coin is that CSIRO may have less to offer industry than it believes. Historically, CSIRO's specific terms of reference have included responsibility for "strategic research" in support of technology. It is also the undisputed case that many divisions have been the source of valuable industrial innovations, and that Australian companies are too neglectful of the value of research and development. But while there is no distinctive economic pattern in Australian manufacturing industry, at least from the standpoint of the export markets, it is hard to see that CSIRO's efforts to reinvigorate the manufacturing sector can do more than spread resources thinly over unknown territory.

Certainly there are many Australian industrialists who complain that CSIRO should not harbour ambitions in this field. Thus Dr Lou Davies, research director of the electronics and defence manufacturer AWA, has publicly said that CSIRO should stay in the patch it knows. Among the division chiefs, who seem to accept the new policy willingly, there seems some confusion about the degree to which basic research, whatever its potential value to manufacturing industry, is permissible in the new regime.

These difficulties could be enormously simplified. Outsiders are bound to ask why a felt need to improve the research base of manufacturing industry should require the retreat from agriculture and minerals. The questions would be more easily decided if there were three distinct organizations for agriculture, minerals and manufacturing industry.

Dismemberment is the least preferred solution at CSIRO, which is natural enough. Fair play, there are other steps that might be taken to make the organization less vulnerable, among which a revision of CSIRO's management structure seems the most obvious.

Over the years, the troika which is the executive has become the day-to-day management; the influence of the part-time members varies, but often requires that able scientists should be involved in the choice of priorities for the years ahead (at which they are not necessarily skilled). It could not but help if this group of people

functioned more like a board of directors of a company, not (as they sometimes appear) a rubber-stamp.

It is hard to think that in such an environment, universities would continue to occupy as marginal a place as they do at present in CSIRO's thinking. The days (in the 1950s) have long since gone when universities were dwarfed in competence by CSIRO. Yet CSIRO does not yet behave as if its remit "to plan and carry out a comprehensive programme of research . . ." could be read as an invitation to place major research grants within university departments. The benefits would

be flexibility, perhaps even lower costs but also the further blurring of the old patronizing relationship between the professional researchers and the teachers.

None of this is to suggest that CSIRO is indifferent to university problems. The physics department of the University of Sydney has succeeded largely because of its past collaboration with the Division of Radiophysics, while the planned Australian Telescope will be a great asset for university groups throughout Australia. But by being more guileful, might not CSIRO also be more effective, and have more friends?

John Maddox

Walter & Eliza Hall Institute

Towards a malaria vaccine

THERE seems no stopping the Gus Nossal show, the Walter and Eliza Hall Institute of Medical Research at Melbourne. At the end of last month, the institute was given by the government one of its largest ever grants — more than \$A6 million over five years for its contribution to the development of a vaccine against malaria. In keeping with the spirit of the times, the government's Industrial Development Board will have a right to 40 per cent of the value of the intellectual property that emerges.

That the Hall institute, technically an independent charity, should win a commanding place in Australian biomedical science is largely the doing of two successive directors, Sir Macfarlane Burnet (1944–65), a 1960 Nobel prizewinner, and now Sir Gus Nossal (since 1965). But being in Melbourne helps. Melbourne medicine, concerned though it may be with the curing of the sick, is also anxious to dominate Sydney, and so is warmly supportive of its own institutions.

Burnet, at 85, is as chirpy as ever. An immunologist before molecular biology came of age, he gave the Hall institute intellectual standing at a time when Australian science was regarded as derivative of that in the United Kingdom. He denies that he has dragged his feet on molecular biology, in his book *Genes, Dreams and Reality* (1971), but argues the need that researchers should be patient. His small-talk (of which there is not much) tends to cosmology as much as immunology.

Nossal is more ebullient, much more the leader (and driver) of men. Austrian by birth, and a protégé of Burnet, almost all his professional life has been spent in Australia. (There were two postdoctoral years at Stanford.) The Hall institute is still small enough (with a staff of 200) for Nossal to continue to function as director of the cellular immunology unit at the institute, one of the eight between which the institute's work is divided.

The most tangible sign of the institute's success is the new building, financed

largely by the governments of Australia and Victoria, into which Nossal hopes to move later this year. One of the institute's frustrations is that the building is at least a year behind schedule, largely because of labour troubles during construction. Nossal says that some features of the design were incorporated into the building at Cambridge, Massachusetts, in which the Whitehead Institute is now housed; he finds it galling that a building on which \$A20 million has already been spent should be so far behind.

The move to the new building, 100 metres away, has been made necessary by the growth of the past few years, and by the need of space in which the institute is now housed. Until the latest grant was announced, the malaria vaccine programme accounted for roughly a quarter of the whole programme, whose cancer research unit has now become a Ludwig institute.

Nossal's operating costs are low by US standards but higher than in the United Kingdom. Last year, the institute spent \$A7.3 million, of which more than a half (\$A3.7 million) came from the federal government's grant-making agencies, chiefly the National Health and Medical Research Council. The Victoria government contributes \$A500,000 a year, while Nossal is proud last year to have pushed the value of grants and contracts from overseas above \$A1 million for the first time (with the help of the Rockefeller Foundation and the US National Institutes of Health).

The malaria vaccine programme is inevitably the most glamorous part of the institute's programme, although Nossal says (before the latest grant) that it accounts for only a quarter of the total effort. In reality, the present excitement is the product of ten years of development at the Hall institute, and malaria (particularly that caused by *Plasmodium falciparum*) is only one of the half-dozen or so parasitic diseases in which the unit has an interest.

The present objective, based on a

knowledge of the genome of *P. falciparum*, is to develop recombinant antigens characteristic of the parasites that may be expected to stimulate the immune response when injected into people. The key development (see *Nature* 306, 751-756; 1983) was the demonstration that antigens characteristic of the blood-stage (merozoite) parasites can be expressed in *Escherichia coli* and that surface antigen, itself a molecule with relative molecular mass of 200,000, contains a repeating unit of eleven amino acids. Since then, the parasitology group has been able to show that peptides derived from naturally occurring *P. falciparum* proteins and containing even shorter repeating sequences of amino acids can react with immune sera (*Nature*, 310, 789; 1984).

So the way seems clear for a systematic programme of work with a high chance that it will lead to the means of immunizing people against malaria parasites carrying the particular antigen investigated. Robin Anders, head of the malaria team at the Hall institute, is nevertheless eager to emphasize the difficulties ahead. The extent of the variability of the antigens between the different strains of just *falciparum* is not yet settled, while the task of working through the genomes of the other species of *Plasmodium* responsible for human malaria has hardly begun.

Another difficulty ahead is that an effective human molecular vaccine will almost certainly have to stimulate immunity against at least two other antigenically distinct forms of the parasite, that carried in the liver and the sexual stages transmitted to the mosquito vector. As a consequence, Dr G. F. Mitchell, head of the immunoparasitology unit at the Hall institute, says that there is now close collaboration with other groups working on these stages, the Nussenzweigs at New York University for example.

Even before the \$A 6 million grant from the Australian government was announced, Nossal was optimistic about what lies ahead. He reckons that it should be possible to tell what the vaccine cocktail should contain and to have laboratory evidence of its efficacy within three years, and that a working vaccine may be used for the first time in five years or so. Nossal is also full of praise for the WHO Special Programme of Research and Training in Tropical Diseases, whose existence coincides with that of the Hall institute's explicit interest in parasitology.

For the rest, the laboratory is up to its neck in cell biology of all kinds. Nossal says there is virtue, nowadays, "in being able to call almost anything immunology". Nossal's own group is engaged on the hunt for the chemical messengers between lymphocytes which are presumed to modulate the immune response, generically the lymphokines; one of its more recent successes has been the characterization (down to amino-acid sequence, in

collaboration with Dr Lee Hood's group in California) of the P-cell stimulating factor (PSF), thought to stimulate the proliferation of haematopoietic cells when released by activated T cells.

On the principle that immunology spans all cell biology, the Hall institute is inevitably involved with questions such as the maturation of T cells in the thymus. (The local doctrine is that only a minority of

thymocytes eventually survive as T cells.) The translocation of the *myc* gene in oncogenesis is just as inevitably prominent in the research programme, but the promise for the future may lie in the programme of the molecular biology unit, which is concentrating on the relationship between oncogenes and growth factors (and the receptors for them) in the causation of cancer. □

Universities

Entangled in red tape

THE universities of Australia are in a state of flux, but that is nothing new. Since the 1940s there has been an almost continuous examination of the function and operation of educational institutions, both universities and the Colleges of Advanced Education (CAE), many of which have evolved from the old state-run teachers' training and agricultural colleges.

The consequences of this selfconsciousness have been beneficent. The system has grown, and is still growing. Among the nineteen universities proper, there is an interesting diversity, neatly illustrated by the differences between, say, the James Cook University of North Queensland (p.195) and the University of Adelaide (p.198). Since the Second World War, the universities as such have also been transformed from undergraduate teaching institutions to institutions with substantial and effective research programmes and graduate schools. So why is there persistent anxiety about the working of the system?

The arrival of the Hawke government in March 1983, with its commitment to more open access, was inevitably a spur to further introspection. There are three sets of issues in the air — budgetary problems (including the question of whether students should be required to pay fees, as used to be the case before the 1974 Whitlam government), support for the direction of research and the management of the system as a whole.

The pursuit of administrative tidiness over the past decade in particular has complicated the management problem. Professor David Caro, vice-chancellor of the University of Melbourne, has said that the administration of higher education in Australia "is the most complex in the world... no other country... has invented such an involved co-ordinating and advisory apparatus".

This is how it works. The Australian universities (nineteen plus the Australian National University at Canberra) are supervised by the Universities' Council, whose existence goes back to the recommendation of the Murray committee in 1956 that Australia should interpose a council similar to the British University Grants Committee between government and the universities; the complication, in

Australia, is that there are two tiers of government, federal and state. Since then, two further higher education councils have emerged, one for CAEs called the Advanced Education Council and one for Technical and Further Education (TAFE). The notion that each of these councils should make separate claims on federal and state government funds was recognized by 1974 to be a recipe for conflict, which the Whitlam government sought to rationalize by creating a Commission for Tertiary Education to coordinate the work of all three councils. The commission came into being only in 1977; the delay in part is explained by the dissolution of the Whitlam government by the governor-general, Sir John Kerr, in 1975.

What now seems clear is that even the new system is unworkable. The newly appointed chairman of the Commonwealth Tertiary Education Commission (CTEC), Mr Hugh R. Hudson, puts the point eloquently in a document published earlier this year, a response to the federal government's request for yet another review of the administration of higher education.

Before 1974, the federal government contributed only 35 per cent of the public subsidy of higher education, the remainder coming from the states, but the Whitlam government (with the agreement of the state governments) took financial responsibility to itself in 1974. The result, according to Hudson, is that the states support "the sometimes unrealistic claims of the institutions" in their territory. He says that in the bidding for funds for the three-year period beginning this year, one university, apparently with the support of its state minister of education, asked for a capital sum of \$A100 million, close on two-thirds of total federal spending on capital development in higher education during the previous three years.

Administratively, the present system is also cumbersome. Each council is expected to produce a coordinated bid for federal funds which is then coordinated into a unified submission by CTC. In effect, Hudson says, much of the work is done twice, the volume of paper delivered to the government tends to confuse by its bulk and contradictions and, in any case,

CTEC's supposedly coordinated advice has often to be submitted before the three subsidiary councils have finished their own documents.

Hudson's complaints will be generally accepted but his proposed solutions are controversial. Hudson would turn all three subsidiary councils into advisory committees, concentrating responsibility in his own CTEC; both the universities and the state-oriented TAFE sector are against the proposed change, although the CAEs appear to think they would gain either from that or from an amalgamation of their council with that representing the universities.

Hudson is less clear in his proposals for changing the federal/state relationship. He asks that states should determine their own priorities for the relative development of the three sectors, which is sensible enough; he also says that CTEC should itself have close relationships with universities and CAEs, which need not prejudice the present sponsorship of universities and CAEs by the state governments; but he shrinks from considering whether there should be some change in the present division of financial responsibility.

Two related themes run through Hudson's ambition for the system — the need that socially disadvantaged groups of young people (immigrants, called "migrants", and aborigines) should have opportunities in higher education, and the need for greater cooperation between the three sectors. The first objective is widely accepted, by the government no less than by individual institutions. The second will raise more serious difficulties, even though there are already several institutions that span the boundaries; Hudson points out that James Cook University offers courses appropriate for CAEs, and that the Royal Melbourne College of Technology provides teacher training as well as TAFE courses. But Hudson is also looking for arrangements under which credit can be given for courses which can then be transferred elsewhere.

Hudson's plan would also transfer to CTEC responsibility for ARGs (p.194). The argument is that there is now no assurance that those winning grants have the resources to use them effectively, that the result would be greater efficiency and economy, and that CTEC could better assess the need for an increase in ARGs funds than would the science department.

The Hudson prescription for administrative reform is certain to be influential; the government will have to respond to it before the end of the year. But the plan to take over ARGs, one of Hudson's admittedly "more distant" goals, is also thought to be his own negotiating ploy, something that can be given away later on. The more serious question hardly ever raised is whether institutions, and universities in particular, might be liberated from the sense of detailed remote control from which they now suffer. □

Students and budgets hit plateau

THE growth of Australian universities over the past decade has been dramatic but has now stagnated, as have the budgets of individual universities. Many now argue that, without saying as much, the federal government is requiring the universities to do more with less.

Student numbers are now some 18 per cent greater than a decade ago (at roughly 170,000). Within this total, there has been a widely welcomed increase of the proportion of women (up from a third to 45 per cent). Since the abolition of university fees in the 1970s the most dramatic growth has been in the numbers of part-time students in the university population: more than a third of undergraduates and 60 per cent of those studying for higher degrees are part-timers.

The universities differ among themselves both in size and in the general character of the courses they provide. The University of New South Wales (mostly in Sydney) is the largest, with 19,000 students, with the Universities of Sydney (18,000), Melbourne (16,000) and Queensland at Brisbane (18,000) not far behind. But even some quite new universities, such as Monash (founded in 1958, now with 14,000 students) and Macquarie (founded 1964, with 11,000 students), at Sydney and Melbourne respectively, have been able to grow rapidly. At the other end of the size scale are James Cook and Murdoch (in Western Australia), with 2,000 and 3,000 students respectively.

During the past five years of near-stagnation, the general response of the larger and thus more flexible universities has been predictable — to concentrate teaching and research on the stronger departments, closing down those that have a lesser contribution to make, and to seek external income by means of research contracts. The decisiveness with which the larger establishments have been able to respond to these pressures would delight the

British University Grants Committee, which for similar reasons in different circumstances is asking for exactly these responses.

In Australia, the Universities Council (one of the three statutory components of CTEC) has done what it can to strengthen good departments by persuading the universities to found ten "Special Research Centres", intended to be centres of excellence within the university system as a whole. (One of the ten centres, a nerve-muscle research centre at the University of New South Wales, was closed soon after being founded in 1982.)

The conditions under which these centres have been founded are exceedingly flexible; within reason, those appointed as directors are able to spend the funds available (up to \$A10 million over five years) on staff and equipment or some blend thereof. Academics and their critics appear to agree that an extension of this scheme would be valuable.

There is much less agreement about steps recently taken by the Universities Council to ensure the efficient administration or research funds in universities. The council's chairman, Professor D.N.F. Dunbar, wrote to vice-chancellors two months ago asking that universities should not "distribute by formula" this component of their recurrent budget, and including the ominous statement that "the present approach, which characteristically allows staff to follow their individual interests" is unlikely to make "the best use of the limited funds available".

For what it is worth, the successful universities are already seized of this need, while the successful university departments are fully aware that the success depends on the recruitment of outside funds. It is not for nothing that Professor Harry Messel, head of the School of Physics at the University of Sydney, boasts of having raised \$A30 million in as many years. □

Australian National University

A bed of "tall poppies"

AUSTRALIA's most unusual university, the Australian National University (ANU), is not so much a university in the ordinary sense as a collection of specialized institutes of advanced study to which there was added (in 1960) an undergraduate teaching establishment fashioned from the pre-existing University College of Canberra.

ANU is financed directly by the federal government, not through CTEC, as are the remaining universities, and for that reason is jealously regarded by academics elsewhere. The jealousy centres not merely on the separate flow of money (\$A135 million in recurrent costs) but on the terms of reference of those ANU academics in the seven research schools (Biological Sci-

ences, Chemistry, Earth Sciences, Pacific Studies, Physical Sciences and Social Sciences), who are required only to prosecute research, and who teach by grace and favour, sometimes at other universities.

Over the years, ANU has turned out to be a powerful means of attracting academics from overseas to settle in Australia. Inevitably, in an egalitarian land where "cutting down the tall poppies" has become the general idiom for the levelling process, ANU has become a focus for controversy. The excellence is not disputed, but academics elsewhere increasingly argue that they have to be excellent to succeed, and have to teach as well.

ANU's defence is twofold: that there is a small army of graduate students, drawn

from all over Australia, and that, in any case, many members of the research schools help out with lecture courses provided for the faculties. But only the research school of chemistry (at the instance of Professor Arthur Birch, the school's first director) is actually contiguous with its undergraduate department.

There is also a certain clubbiness about the relationship between the federal government and ANU. Last month, one member of the university described in a quite different context how he had been able to win support for a project by inviting a minister to a dinner. The research school of chemistry was apparently brought into being at a dinner in London (England) at which Sir Robert Menzies (then prime minister of Australia) and Professor Arthur Birch were both present. If those who would cut down tall poppies can be persuaded to stay their hands, there may be an interesting future.

The other easy complaint to make against ANU is that, not being part of the university system as a whole, it is not subject to the pressures of which other Australian universities are repeatedly reminded, that an academic's first responsibility is to make Australia prosperous. ANU's answer is quick and disarming: we do. And broadly speaking, ANU is right.

The research school of Earth sciences has Synroc to boast about; Australia has high hopes that this will become the world's preferred way of sorting radioactive waste. The School of Physical Sciences has spawned what must be one of Australia's most unusual companies, Optical Fibres (Research), which has received a grant of \$A5.4 million from the Industrial Development Board to develop a range of small sensitive sensors based on the fidelity with which plane-polarized radiation is transmitted uncorrupted through optical fibres subjected to various external conditions. Significantly, this development is an offshoot of the department of applied mathematics at the school.

To a hurried visitor, there is no difficulty in understanding why ANU is attractive to those who work there, or in accepting the claim that the institution has fulfilled the hopes of the university's founders that it would become a creative force in Australian intellectual life.

With the passage of time, and especially as the research schools at other universities have been strengthened, collaboration between ANU teams and others has become prominent, and should grow. To the extent, of course, that the need for such an institution has been diminished by developments at other universities, the question naturally arises whether ANU should continue indefinitely to exist. The simple answer is that it would be unthinkable, even in Australia, to cut down such a tall poppy; the best solution must be to turn the institution into a truly integrated university, eroding the present gulf between teachers and researchers. □

Research support

Catholic scheme for grants

AN academic scientist without a grant is like a magician without a silk hat (from which to produce rabbits); he may be able to manage but there is a danger he will not try. That is one reason for sharing the alarm now voiced annually by the Australian Research Grants Scheme (ARGS), the only source of funds for research in general, as distinct from biomedical research or one of still narrower sectors (marine science, for example) to which the Commonwealth government has accorded priority. Each year, the managers of the scheme (academics to a man, but working to the Ministry of Science) ask for more with a despair that outdoes preceding displays of outrage.

The scheme dates from the recognition 20 years ago that Australian universities had somehow equipped themselves, against earlier traditions, with people capable of research of the highest standard, and of teaching graduate students. In 1965, the federal government thought that £A1 million (then the Australian currency) might suffice, which it may have done. Now the complaint (familiar elsewhere) is that the budget has shrunk to less than half of what is needed to support all worthwhile projects. This year (1985) only a quarter of the new applications judged worthy of support won grants.

Everybody, even the government, seems to agree that this is unacceptable; but then nothing happens.

With appropriate adaptations to Australian geography, the scheme is much like those in operation elsewhere. People apply for grants at the beginning of each year, all applicants are interviewed (by an itinerant subcommittee) and grants are awarded on the recommendation of a committee (chairman, Professor Peter Sheehan, University of Queensland) by the Minister for Science. Applicants may be from any discipline, and need not even be academics (but invariably are).

The committee in charge does not mince words. "Funding for ARGs is dismal", it says in the introduction to the report on this year's allocations, after cheekily quoting Prime Minister Bob Hawke as having said a year ago that his government intended to support "excellence in research wherever possible".

Part of the trouble seems to be that the government's own rhetoric about the importance of research has increased grant applications while the budget has merely kept pace with inflation. This year, there was \$A23.9 million to spend on 2,359 applications that would have cost \$A66 million. As a consequence, according to the committee, 15 per cent of the 1,000 plus projects begun in earlier years had to be brought "prematurely" to an end. In constant money, the present budget is less than that a decade ago. The average

annual value of a grant has fallen to \$A19,478, compared with \$A24,475 (a 1984 price) in 1975.

There is more to these complaints than empire building. The committee considers that its function is to cater for academic research in the round, whence the mixture of programme and project grants, equipment grants and career fellowships (for postdoctoral people). It rightly boasts of having backed a number of important projects, the programme for the *in vitro* fertilization of animals (including humans) among them.

For the years ahead, the committee has identified a number of new directions or which it would embark. Modestly, it asks for an extra £A3 million for equipment for 1986 (to double that spent this year) and money for supporting 30 postdoctoral fellows and 20 postgraduate students (to be attached to the better projects). It would like to be able to offer the ablest applicants a measure of long-term support and asks for \$A500,000 to spend in 1986 or schemes that will help to put Australia on the international intellectual map.

If everybody agrees that ARGs is a deserving cause, and that it is run well, why does its budget grow at such a modest rate? In the climate of Canberra, political explanations are unavoidable. Why should politicians increase the budget of an existing organization and run the risk of being called spendthrift when they can just as easily commit a few million dollars a year to some special scheme (as well as for marine science, there are now special grant-making schemes for biotechnology, energy research and water research) and gain the credit for a new initiative? Surprisingly, nobody complains at the earmarking of funds, but people say that the

Support for higher education

In recent years, the funding for undergraduate education has slipped behind that for schools

multiplication of grant-making committees is a nuisance.

On or just above the horizon, however, there are at least three ways in which the future of ARGS will become a political issue. The most immediate is the demand by the chairman of the Commonwealth Tertiary Education Commission that ARGS should be administered alongside the universities (see p. 192). The argument is that it would be simpler that way. Academics seem to agree with Don Aitkin, professor of political science at the Australian National University and deputy chairman of ARGS, that the demand has been made only to be bargained away in return for some other concession at a later stage. They may have reckoned without Mr G.S. Hudson, the commission's chairman.

The ARGS budget, although less than 10 per cent of that of CSIRO, also touches the credibility of the science minister, Mr Barry Jones. The Hawke government is generally thought to have committed itself to increasing the budget by 10 per cent a year, and for 1984 did better. But last year, Mr Jones emerged from the budget fixing with only 6 per cent extra for ARGS. The outcome may say more about the relationship between Mr Jones and his colleagues than about the government's commitment to science (see page 188), but many see it as an election promise abandoned after victory at the polls.

Moreover, even academics who do not need ARGS or who are prevented from using it (as are those at the Australian National University) think the budget a disgrace. ASTEC has consistently said the funds available for research should be increased. No doubt its forthcoming report on research in Australia will repeat the message, perhaps more persuasively. People relate with black glee the tale of how in 1976 the grants budget was arbitrarily reduced because the then minister had not understood the difference between the financial and the grant-making year, which, they imply, just shows the indifference of governments to research. Unless the government is careful, ARGS could become an issue that divides it from the technical community.

There are alternatives to merely spending more. The Tertiary Education Commission's scheme for endowing centres of excellence (if continued and increased) is a means by which young able people can become established. Even the earmarked schemes can get people started, while it may seem to a government repeatedly made aware of over-academic university systems elsewhere that it may reasonably calculate the maximum restraint is the best policy, at least for the time being. The dilemma it must resolve is whether it makes sense to continue producing potential researchers whom industry will not employ and who cannot pursue their craft with government funds.

The scheme's policies are catholic.

While most successful applicants are at universities, the scheme can be used by people working at, say, state museums. Emeritus professors have a chance. The committees try to concentrate on certain fields (such as ionospheric physics or the mathematics of category theory, pioneered at the University of Sydney).

Grant applications reflect laboratory housekeeping needs. More than 60 per cent of the total sum awarded goes on salaries (for research assistants), less than \$A1 million (in 1985) is for applicants' travel, almost all of it within Australia.

Among the scheme's university clients,

successful researchers say that awards are generally too small, and do not obviate the need for supplementary funds from elsewhere. There is also a certain amount of grumbling by people in the natural sciences that the humanities and social sciences should consume nearly 20 per cent of the total, and on the other side of the fence, shock-horror at the sums spent on physical equipment. But the committees awarding grants insist that they work well together, and that ARGS should not be split. A better course would be to bring all the government's research grants schemes together. □

James Cook University

University of the Tropics

ONE of the occasional hazards of the James Cook University is to come in in the morning and find seven feet or so of python wrapped around a pipe in one's laboratory. The trick, apparently, is not to panic but to unwind it (or even better, have someone else unwind it) and put it somewhere useful, which according to Professor Campbell, of the Tropical Veterinary Science School, would best be the hay-shed, where it can perform the useful service of keeping down the mice.

Pythons, and some other snakes on which it would be singularly unwise to tread, well demonstrate what foreigners sometimes forget: that much of northern Australia lies firmly in the tropics (Australians simply forget that anybody lives there). Townsville, where James Cook University is located, is actually just 19° south of the Equator; close by are both arid tropical areas and tropical rain forests hardly different from those of Java. These environments, plus the Great Barrier Reef — 2,500 or so reefs stretching 2,000 miles along north Queensland's coast, with Townsville lying roughly at the centre — give James Cook University its special

character. It is the only university in the developed world that lies in the tropics, and has immediate access to tropical ecosystems.

The university itself is quite small, with just 3,000 students, but it has a unique facility in its tropical veterinary graduate school, set up in 1969. Against a background of declining university expenditure, the school has been able to expand steadily as demand for trained researchers in animal health and production has grown throughout the tropical world. At present, there are 60–70 graduate students with almost as many from South-East Asia as from Australia. There are close links with Indonesia and some 14 scientists work full-time at a research institute for animal diseases set up by the university at Bogor, with funds from the Australian Development Aid Programme.

Of major significance is their work on the filarial disease onchocerciasis, which in humans can cause blindness. Because filarial disease is also widespread in local cattle, in which it causes no more than lumps in the muscle, potential anti-filarial drugs are being tested in a pro-

The underwater laboratory developed at James Cook University — sponges are being incubated at a depth of 10 metres.

gramme supported by the World Health Organization.

Elsewhere, everyone seems to be making use of the opportunities offered by the Great Barrier Reef. The biologists, who offer the only degree course in marine biology in Australia, have progressed from completion of coral taxonomies to studies of reef community structure, reproductive ecology and population dynamics. Physicists have been modelling storm conditions, and engineers designing structures to keep out the box jellyfish (sea wasp) which makes swimming dangerous for more than half the year. Altogether, the university has been able to produce well over 100 papers in marine biology, from 11 different research sections, in a single year.

Even the chemists have managed to exploit the reef. Marine animals are an almost untapped reserve of natural chemical products, many of which have pharmaceutical potential. Early work was triggered by the Roche Institute of Marine Pharmacology at Sydney; with that institute's demise, interesting looking chemicals go to a US pharmaceutical company and the thrust of research has turned to finding out why the soft corals are so good at not being eaten by predators. (The answer is that they are full of terpenes,

A novel approach to university architecture at James Cook.

which not only deter predators but can be released to kill nearby hard coral, allowing the soft coral to overgrow it.)

The university even has its own miniature marine institute in the shape of the Sir George Fisher Centre for Tropical Marine Studies, named after the university's first chancellor. Here again, there is interest in natural product chemistry, but with a novel twist — the species studied cannot be kept in an aquarium so the laboratory bench is moved to the sea bed. The centre also keeps the Australian Collection of Marine Micro-organisms, as yet virtually unknown outside Australia, including more than 170 blue-green algae and two hundred bacteria, including petroleum degraders.

For geologists, the university's attraction is not so much the reef, but that half the nation's mineral resources lie north of a line drawn through James Cook, a region with no other university to serve it. To exploit their situation, the geologists have set up an Economic Geology Re-

search Unit (EGRU). In return for an annual membership fee, the hundreds of exploration geologists who roam the north can find a home to analyse samples and consult maps. Although EGRU is essentially one largish room equipped with geological and topographical maps and Landsat images, access is also given to departmental facilities including a scanning electron microscope. The centre has clearly been a success; numerous companies have signed up, which in turn has helped recruit funds for work carried out in the department, providing input into an MSc course in exploration and mining geology.

This neat tie-up with business does not,

however, prevent the head of the geology department, Professor Bob Carter, from pointing out Townsville's big disadvantage — isolation that means political isolation from the decision-making and grant-giving heart of Australia and, more important, isolation from fellow scientists. With 12 full-time staff, 15 PhD students plus a few research fellows and a yearly travel budget of just \$A2,500 (a return ticket to Sydney costs \$A700), the complaint is natural. Fortunately, the reef provides a bit of help. Now that Townsville has an international airport, quite a few scientists on round-the-world trips stop off to see the reef, dropping in at the university on the way. **Alun Anderson**

University of New South Wales

Appealing to industry

SYDNEY'S "other" university, the University of New South Wales, complains like the rest of them at the steady erosion of its budget (by an estimated 2 per cent a year). But it is big enough, with 18,000 students, to be flexible in the management of its affairs. It also has the unique benefit of an agreement with the federal government to operate the Australian Defence Force Academy, more than 100 miles off-campus at Canberra.

Chartered only in 1952 as a technological university, the institution has a flavour of diversity. As well as medicine there are faculties of applied science, architecture and law. Humanities are big, while the arts faculty is both a leavening for the rest of the curriculum and a valuable contribu-

tion to Sydney's cultural life.

Financially, the university continues to grow, but only by means of research grants and donations. Although the federal government's grant (at \$A125.6 million) was unchanged between 1983 and 1984, the administrators complain that the inflation factors used by the Commonwealth Tertiary Education Commission do not adequately compensate for the inflation of academic costs. But the university is now raising more than 21 per cent of its income from other sources, most of them public funds such as the ARGS (see p.194). There is, however, an invaluable \$A4 million income deriving from investments, a pot of gold worth \$A54 million (which should surely be yielding more).

The university typifies those among the larger universities who see their future as one in which they will be increasingly dependent on what they can earn by research and other means. There is, for example, a university company (called Unisearch Ltd) which promotes the role of its academics as industrial consultants, and which also handles joint research contracts and even the exploitation of patents; gross income last year exceeded \$A2.58 million.

Not surprisingly, the search for outside funds runs into the familiar conflict between academic and commercial interests. Professor Raymund Golding, the pro-vice-chancellor for administration, says in the annual report just published that potential industrial partners cavil at the payment of an element of overhead costs and also think they should in some sense "own" the results of successful projects. If what people say about Australian industry's regard for research is true, the learning process will be slow.

The search for outside sources of funds is one of the reasons prompting the creation in the past few years of a series of topic-based interdisciplinary centres with responsibility for teaching and research. Uniquely, it is claimed, there is a centre for law and technology, and others dealing

Popular science

MAKING science public in Australia falls to a variety of agencies, of which the best known and most frequently disappointing is the Australia and New Zealand Association for the Advancement of Science (ANZAAS), whose 1985 meeting will be held next month in Sydney. The Australian Academy of Science does a valuable service, but of a different kind, having become over the past decade a first-rate school textbook publisher.

But Australia's most vivid source of news about science is the Australian Broadcasting Corporation's output of sound radio, and in particular the series of regular programmes built around the weekly programme *Science Show*. The producer, Robyn Williams, says that ABC has given him the chance during the past decade to try a variety of formats. The programmes are both popular and arresting. Especially now that they are complemented by programmes ranging from straight-forward but informal talks to general information about the use of computers, they have contributed to the high awareness of policy on science and technology in Australia. □

Kangaroos thriving but still threatened by drought

DESPITE rumours to the contrary, the kangaroo is alive and well and living in Australia. In recent years, there has been considerable concern, and international pressure, over their commercial killing and some fears that kangaroos could be endangered. Although criticism over hunting methods may still stand, sophisticated aerial surveys show that there are still plenty of kangaroos.

"Kangaroo" is not in itself a scientific term and generally refers to the man-sized members of the Macropods, usually the red kangaroo (the favourite at zoos) and the two grey kangaroos. Among smaller members of the group, the wallabies and rat-kangaroos, there are six endangered species and several others that are rare, although none is commercially hunted.

It is almost two hundred years since the kangaroo was first exhibited in London, at the Lyceum in the Strand; admittance was seemingly expensive at one shilling, but perhaps not for "an Ocular Demonstration [which] will exceed all that words can describe, or pencil delineate ...". And from that time, kangaroos have been killed for meat, for their skins or simply as pests, by gun by poison or by simply rounding them up and clubbing them to death by the hundreds, in the "battue" that occupied sporting Australians in the nineteenth century.

More recently, kangaroos have become a subject of fierce controversy; some would have them totally protected as a unique symbol of Australia, some believe they should be destroyed as pests because they

damage fencing and sheep pastures, while some hold that they should be managed for maximum profit as a renewable resource. International pressure has come from the United States where conservation groups succeeded, in 1974, in having red and grey kangaroos listed as a "threatened species", and the import of kangaroo products banned. The ban was later lifted after Australia was able to demonstrate that kangaroo

resources are properly surveyed and managed. All seemed set for them to be removed from the US list of threatened species but in April 1984, the US Fish and Wildlife service ruled that the severe 1982-83 Australian drought had put the status of kangaroo populations in doubt once more.

The latest evidence suggests, however, that kangaroos may be even more abundant than before European settlers ar-

rived. Thanks to work by Graeme Caughley of the CSIRO Division of Wildlife and Rangelands Research, kangaroo populations can now be accurately estimated from the air. The trick is to fly a series of transects, at a particular height and speed, counting the kangaroos within a 200-m strip marked by streamers trailing from the aeroplane. Not all kangaroos are seen but a set of equations, devised by Caughley is used to correct the observer error according to the type of countryside. When these results are compared with sightings of kangaroos recorded in early explorers' diaries, it does seem that the kangaroos are more abundant than ever before. The probable explanation is that the provision of water-holes for sheep and the reduction of the predatory dingo population have removed constraints on the population.

Commercial taking of kangaroos is now very strictly controlled in all states. Unlicensed hunting is prohibited. But it is unlikely that protest will diminish over the seemingly brutal way in which kangaroos are taken by dazzling them at night with bright lights and finishing them off with clubs. Such practices have gained international notoriety; when the Japanese were under fire last year for whaling, from Australian conservation groups among others, Japanese newspapers ran pictures of Australian kangaroo hunting with a headline raising this awkward question "How can they criticize us?" This is a point the Australians might take.

Alun Anderson

with the ophthalmology of contact lenses (a local speciality), industrial relations and the Japanese economy. To label a group of academics thus may either be a way of simplifying the task of giving outsiders special advice in the form of custom-designed courses or a way of attracting research contracts credibly.

One of the most conspicuous of these centres is also the most unusual, consisting of a collaboration between the university and the Royal Melbourne Institute of Technology. (Sydney and Melbourne are generally linked together only by their rivalry.) The funds for the venture (\$A2 million) were originally provided (in 1982) by the federal government, then founding ten industrially oriented research centres at universities. More recently, the centre has made a deal with the Australian subsidiary of IBM which may not be a direct source of income but which extends the scope of the operations.

The centre's proudest boast is to have produced what are the most efficient solar cells so far to have been made of amorphous silicon (see M. H. Green *et al.* *Appl. Phys. Lett.* **44**, 1163; 1984). The trick is to coat the surface of a piece of silicon (doped with phosphorus by diffusion from the upper surface) with a layer of silicon oxide between 20 and 50 ang-

stroms thick, using a technique developed by M. H. Green over the past decade. The insulating layer inhibits recombination of electrons and the holes from which they have been quarried; electrical contact through the upper, exposed, surface of the cell must be accomplished by a network of metallic fingers evaporated onto the surface. The highest efficiency claimed so far is 19.1 per cent (with an open-circuit current of 0.64 milli-ampere).

Nobody pretends that hand-built cells like this (the standard size is 2 cm square) will be mass-produced so as to meet the world's (and Australia's) need for energy. The next goal, at the centre, is to push up the efficiency to 20 per cent or more. In the process, the centre argues, people will learn to understand what design parameters are needed to build an efficient, and cheap, solar cell. And in any case the laboratory will become even more familiar than at present with the technology of making semiconductor devices; it has ambitions to use thin films of insulators in more conventional transistors.

The facilities at the centre are not very different from those to be found nowadays in microelectronics laboratories elsewhere in the world; the University of Edinburgh in Scotland is, if anything, better equipped. But the joint centre gives

the University of New South Wales (and its Melbourne partner) the chance to acquire and improve basic skills in an important field and, with luck, evens the chance to strike gold one day. The federal government's investment seems to have been worthwhile; next month's budget will show on what scale it is to continue.

For the university as a whole, this is only one of a great many developments that should collectively give the lie to the federal government's suspicion that Australian academic institutions contribute too little to social and economic well-being. Visitors from a land of small universities such as Britain are bound to be impressed both with the financial robustness and the intellectual diversity of a really large university. New South Wales is large enough to be flexible about student entry (more than a quarter of the students are part-timers, a proportion growing towards a third are women) and even to mount special programmes for aborigines and students from other sectors of higher education without formal academic qualifications. It is also large enough not to be ashamed to have an international reputation both in the anatomical description of the mammalian retina (as by Dr Jonathan Stone's group) and the mechanical and optical engineering of contact lenses. □

Adelaide University

The sweet smell of success

THE University of Adelaide's compact campus embodies the whole range of responses to the overall decline of funds for basic research facing Australia's scientific community. Barring a last-minute reversal, the university is switching resources away from science; seven posts are to be taken from the Faculty of Science this year, and transferred into commerce, law, women's studies and engineering. But, at the same time, the university has set up its own venture development enterprise and encouraged new joint ventures with industry, which are now flowering in a number of departments.

Those whose subjects are currently in vogue find little to complain of, and several departments have managed to win various species of the government's new grants. But for those in areas of basic research now out of fashion, or without immediate appeal to industry, the outlook is bleak.

Physics is likely to be one department affected by the shift of jobs to elsewhere in the university, even though the demand for physics graduates is as high as ever, according to annual surveys conducted by the department's head, Professor John Prescott, and despite a recent series of major discoveries by the cosmic ray group. Using the only detector of energetic cosmic-ray showers in the Southern Hemisphere (home-built at a fraction of the cost of others), they have discovered two of the three known sources of ultrahigh energy X-rays — binary X-ray stars in Vela and the Large Magellanic Cloud (see *Nature* 315, 205; 1985).

Good work is also being done by the atmospheric physics group which has installed the first middle-atmosphere radar in the Southern Hemisphere, and by a group interested in the solid-state physics of thermoluminescence dating. They now claim the most sensitive thermoluminescence spectrometer in the world. Not surprisingly, there is a deep sense of frustration that sufficient funds are not available to build on the department's achievements, nor to stop talented workers slipping away to the United States.

Professor Prescott sees Australia's level of spending on science as "appalling" and points out that Australia is seventeenth among the 21 OECD countries in terms of research and development spending as a percentage of gross national product. But that does not mean that all hope has been abandoned: one member of the department, fresh from CERN, is campaigning against all odds for Australia to take up high-energy physics.

A more optimistic outlook on life prevails in the geology department, where Professor David Boyd has just had the go-ahead (and \$A150,000 a year) for a "key" centre, one of the Commonwealth

Tertiary Education Committee's new concepts to promote areas of "special economic and social significance". The key centre is for advanced studies in petroleum geology and geophysics; ten people a year will enter a two-year course and there should be plenty of jobs waiting for them, given the probable acceleration in the pace of oil exploration. Professor Boyd has spent a major part of his own career in industry and the new course will involve the Australian Mineral Foundation, an industry-financed independent institute running advanced workshops. The aim is to mix students with other people in industry; that will, in turn, help industrial funds flow into the department.

In biochemistry, there is also the sweet smell of success. A "centre of excellence" was created in 1982, with a \$A1.2 million grant over three years; this has now been followed by \$A1.6 million for the next three years. The Commonwealth Special Research Centre for Gene Technology, as it is officially known, carries out fundamental research on gene regulation under Julian Wells.

Within that huge area, there are projects on the activation of genes that metabolize drugs in the liver, the isolation of wool keratin genes, plant viruses and viroids, tissue-specific expression of histone genes and the use of recombinant DNA technology to produce growth hormone. Virtually all the projects are planned with some direct application in mind. The drug metabolism studies relate to the human disease porphyria. Studies on wool show cysteine to be a limiting factor for growth, so the ideas of introducing cysteine synthesis genes by embryo microinjection is being explored. Viroid probes can allow

the early detection of economically important plant diseases, and so on.

Indeed, the group has already gone into the commercial business by setting up BRESA — a wholly university-owned biotechnology company. Eight full-time researchers are already at work for the company and have one best-selling product — photobiotin — which allows the simple light-activated coupling of biotin to DNA and RNA probes.

The microbiology department also hit the jackpot last year with the acquisition of a \$A870,000 grant over three years from the government's new National Biotechnology Programme. The grant went to Professor Derrick Rowley for a collaborative project with industry — in the shape of F.H. Faulding and Co. Ltd, a successful local pharmaceutical company, for the development of oral vaccines against enteric diseases. A joint company "Enterovax" has been set up, employing 14 people on research within the microbiology department.

It is not strange that the biologists are now getting the cream of the grants, for the government has to some extent recognized the potential of biotechnology. (Biologists also tend to mutter that physicists had their day of riches in the past; now it is the biologists' turn.) But that said, only seven per cent of applicants for funds from the National Biotechnology Programme received anything at all, an astonishingly high rejection rate which has led to complaints about the programme content, the level of financial support and even the competence of the grant authority. Competition for "key" centre funds was also severe with some very disappointed applicants with excellent schemes. Adelaide University (or at least some parts of it) must therefore count itself among the blessed.

Wildlife research

Vermin are out — fauna in

AUSTRALIA'S interior contains a veritable menagerie of the descendants of settlers' domestic animals. Besides the rabbits, there are wild donkeys, horses, goats and pigs; enough camels to provide for a roaring trade in their export to Saudi Arabia; and, in the tropical wetlands east of Darwin, around a half million water buffalo. It is not surprising then, that the principal wildlife research organization, CSIRO's Division of Wildlife and Rangelands Research, carries out an inextricable mix of research on pests and on wildlife behaviour, ecology physiology and conservation.

The division is itself a recent marriage; the Wildlife and Rangeland Divisions were formerly separate, but it was felt that in these days of ecosystem studies, there was no further virtue in keeping plants and animals apart. The division provides for

long-term fundamental studies; shorter-term and day-to-day management problems of conservation areas remain in the hands of the park and wildlife services of the states.

Australia is well covered with parks of one kind or another. Of the total land area, 3.7 per cent (28 million hectares) is specifically reserved for nature conservation. State by state, the proportion of land set aside for conservation varies greatly, reaching 25 per cent in the tiny Australian Capital Territory and 14 per cent in Tasmania, but is less than 1 per cent in the sparsely populated Northern Territory. The Great Barrier Reef is protected by a specially constituted Marine Park Authority.

The division responds to requests for fundamental research from the various states, and also takes on work funded by

Laying down the law on wildlife protection

TRAVELLERS beware! On your stop-over in South-East Asia on the way to Australia, do not be tempted by souvenirs of ivory, exotic butterflies, bird feathers or shells. If you succumb, a gaol sentence may await you.

From May 1984, Australia has had what are probably the world's strictest laws regulating the export and import of wildlife and plants. The native fauna of the nearby developing countries could be ruined by tourists prepared to pay fabulous sums for exotic souvenirs. But the new act provides for up to five years' imprisonment and a \$A200,000 fine for those so tempted.

Indeed, the new laws were considered so strict that \$A0.25 million was spent publicising them before they came into effect — and two gold medals for the best advertising campaign of the year were won in the process. Australia's action will undoubtedly help stop regional trade in endangered species; if Japan could be induced to take similar tough action, real progress might be made.

Responsibility for administering the Wildlife Protection (Regulation of Exports and Imports) Act lies with the Australian National Parks and Wildlife Service

(ANPWS), set up in 1975 as the principal adviser to the Commonwealth government on national nature conservation and wildlife policy. This duty includes the job of representing the government at CONCOM, the council of nature conservation ministers drawn from all the states, and on international bodies such as the International Whaling Commission.

ANPWS also has responsibility for some 5,000 galleries of paintings — all of them out of doors, on rock, and some 40,000 years old. That makes them by far the oldest paintings in the world, and according to Professor J.D. Ovington, the service's director, they are also "among the most beautiful".

The paintings are all in Kakadu National Park in the Northern Territories which, along with Uluru Park (Ayers Rock and Mount Olga) and Christmas, Norfolk and other island territories, are administered directly by ANPWS.

The aim is to set standards that state authorities will emulate (although some may not like to hear that). Certainly, considerable praise has been won for the Kakadu Park's involvement with the local aboriginal community; older people have

been appointed as cultural advisers and many younger people have been trained as park rangers.

ANPWS also has sufficient funds to assist directly conservation programmes of national significance. Needs are diverse and last year the service helped more than thirty projects, ranging from a national plan for dealing with mass strandings of whales to the use of airborne scanners to map vegetation. Odd situations arise; when Vietnamese refugees with quite different eating habits arrived in the country in large numbers, there emerged a risk that they might decimate some marine animals that Australians had not thought of as food.

On a more mundane level, ANPWS produces a staggering output of educational literature — part of which includes the postcards shown above. Indeed, if the number of posters and brochures on Australia's unique wildlife and the masses of endangered species leaflets and stickers are anything to go by, exemplified by the postcards shown above, Australia is well on the way to becoming the world's most conservation-conscious nation.

Alun Anderson

the various agricultural product boards and the like. Some 12 per cent of its \$A8 million budget comes from such outside sources.

Thus the Wheat Board is now supporting research on one of Australia's more bizarre problems: the so-called "mouse plagues" that erupt at four to twenty year intervals in the wheat belt of south-eastern and eastern Australia. Between plagues, mice are rare and of little economic account. When a plague gets under way, they appear locally in their millions producing, as one surrounded householder put it, "a moving carpet of mice, in some places three and four deep... when you walk you tread on them and they run up your legs".

The mice eat everything they can; crops, seeds and the wiring and upholstery out of cars, tractors and harvesters. They penetrate through wooden walls, devour furniture and clog up irrigation pumps. In a 1979 plague in Victoria, \$A15–20 million

was counted, but that is probably an underestimate; a considerably less severe plague in 1984 caused \$A30 million worth of damage.

The problem is perplexing, for the plagues are local and sporadic. Work by Trevor Redhead at the division indicates that the essential trigger for a plague is above average rainfall in autumn which lengthens the time for which the mice can reproduce in winter. But the mechanisms by which the population build-up can reach "plague" levels is far from being understood.

The division's work is not all plagues and pests, however. Basic work by L. Braithwaite on tree-dwelling marsupials, the possums and gliders, suggests that changes in logging practice could reduce the impact of commercial forestry on their populations. The eucalypt forests in which the animals live are commercially exploited, and conventional wisdom has it that harm to wildlife can be avoided by

cutting alternate plots of land in a long-term cycle. But the real situation is not so simple: the marsupials prove to have very marked preferences for certain trees, preferring the so-called "peppermint" eucalypts. This turned out to be because the leaves of the peppermint eucalypt contain high levels of nutrients and so can provide more food for the leaf-eating marsupials and more insects for the insect-eating marsupials.

The Forest Commission has taken note of the patchy distribution of fauna, but a problem remains. The nutrient-rich trees grow preferentially on nutrient-rich soil, much of which, because of its economic potential as farmland, is in private hands. So as is common in wildlife research, the future of the possum and glider marsupials must be passed from scientists to politicians. A way to resolve a potential clash of interests between the needs for faunal conservation and agricultural production must be found.

Alun Anderson

Nuclear energy

The slumbering giant

WHATEVER can have happened to nuclear energy in Australia? A quarter of a century ago, the Australian Atomic Energy Commission, like all its counterparts, was busily designing a nuclear reactor, urging on the exploration for uranium (for which it was the government's sole agent) and even dropping heavy hints that peaceful nuclear explosions might be used to create harbours in the otherwise inhospitable west coast. Australia still contains the world's largest reserve of uranium ore, more than a quarter of the world's total, but otherwise there is a deathly silence.

What has changed? The political temper of Australia, which is not the same as party politics. Australia has acquired in the past decade a detachment from the world of powerful alliances. The close alliance with Britain, now seen as subordinate membership of the old Empire, has long since faded (and may entirely disappear when Judge McLelland's report on British nuclear testing in Australia appears later in the year). The brief flirtation with the United States in the 1960s (Australia was the only other country to send a force to Vietnam, and its then prime minister invented the phrase "All the way with LBJ!") has also withered, as Australia looks more closely around the Pacific rim.

Just over a decade ago, people in Australian television talk-shows were forever arguing about the wisdom of exporting raw materials to economic rivals; why not add the value here, in Australia? Better leave the minerals in the ground, some said. Since then, the long-standing Australian concern that others should not make weapons from its uranium has been strengthened, not least by the French nuclear tests in the Pacific. All political parties include a powerful section of opinion that uranium should be left in the ground. Mr Hawke's Labor Party is riven on uranium policy.

The dilemma for the present government is that the political risk of governing the opponents of uranium mining are offset by the political risks there would be in losing all those jobs, not to mention an export trade worth upwards of \$A2,500

million a year. (Coal exports, now running at \$A4,000 million, are worth even more.) That, no doubt, is why, in November 1983, Mr Hawke asked the Australian Science and Technology Council (ASTEC), and its chairman personally, to study "Australia's role in the nuclear fuel cycle".

ASTEC's response, published last May, failed to resolve the dilemma. The committee endorsed the traditional Australian view that uranium suppliers should do everything they can, by imposing conditions on the uses to which their uranium may be put, to inhibit the proliferation of nuclear weapons. But the council's report went on to say that exports should not be limited "as a matter of principle" but instead should be permitted under stringent conditions. And after endorsing government policy on the control of nuclear weapons (suggesting, in passing, that Australian bilateral agreements should be published as models for other suppliers) went on to argue for Australian participation in "stages of the fuel cycle other than mining and milling" if that will help strengthen the "non-proliferation regime".

Last summer's Labor Party caucus on uranium policy was apparently contentious. This may have been when Mr Barry Jones, Minister for Science, blotted his copybook by opposing the ASTEC recommendations (see p. 188). In the event, Mr Hawke was forced to announce the rejection of the two contentious proposals: mining would be allowed at only a third mine in South Australia if that proved economic, Australia would not participate in other stages of the fuel cycle and this decision will not be reconsidered at least until the end of 1987 (by which time there will have had to be another general election).

Opinions remain divided. The case for doing something to the uranium, enriching it in uranium-235, for example, had seemed strong enough until last year for the Atomic Energy Commission to be hard at work on the centrifuge enrichment process; now that programme has been converted into what is described by Dr D. G. Walker, the director of the commission's laboratory at Lucas Heights, north

of Sydney, as a study of the applications of anti-proliferation measures to the centrifuge process.

Against the background of the Hawke announcement, it is a little strange to find that the Lucas Heights establishment has shrunk since its peak a decade ago. There are around 1,000 employees; most of the fall from 1,300 a decade ago is explained by the transfer to CSIRO of the previous programme of research on unconventional energy sources. Yet nobody seems worried about his job.

Part of the explanation is Synroc, the name for the project that has grown from the advocacy of Dr A.E. Ringwood, from the Australian National University, that would incorporate highly-active waste in synthetic rock. Ringwood's process, not yet proven with radioactive materials of the kind for which its use is planned, has given Lucas Heights a new lease of life. The commission has signed agreements on collaboration with the United Kingdom and Japan.

For the rest, the establishment has three functions. It is a major source of short-lived radioactive isotopes not merely for Australasia but occasionally for more distant customers. (West German non-destructive testers used to buy substantial amounts of ytterbium-169.) More recently, the establishment has developed a neat way of extracting technetium-99 from the fission product molybdenum-99 in such a way that physicians can extract small amounts of this useful tracer when needed simply by eluting it from alumina.

Lucas Heights is also a general-purpose research establishment (in agriculture, hydrology and nuclear physics) and a teaching resource (with a 3-MeV Van de Graaff machine used chiefly for fission studies). What would be said of a uranium-exporting country that had no means of telling what fission is?

The third function is advisory. Simply because of the government's interest in proliferation, a small army of experts in the field is a necessity. This need is unlikely to vanish. And in any case, Lucas Heights is a nuclear development establishment in waiting, the kind of place that would be needed if a change of policy came along.

The critics of Mr Hawke's uranium policy are of two kinds, those who would leave the material in the ground and those who hold that it is too restrictive. The next dispute is likely to blow up when the commission asks for a replacement for its HILAR reactor, modelled on a British reactor built in the 1950s. Dr M.H. Brennan, the Sydney physicist who is also the commission's chairman, thinks the request cannot be long delayed. Others go much further, pointing out that there are already many remote parts of Australia where a cheap and small-scale source of nuclear electricity would be a boon. And the present economic upheaval may make many people regret the loss of all that value added. □

The leading producers of uranium (non-communist countries)

Country	No. of plants	Capacity (tonnes per yr)	Estimated reserves (tonnes)
United States	33	13,750	131,300
Canada	5	8,540	176,000
S. Africa	15	5,780	191,000
Niger	2	4,450	144,000
Namibia	1	4,250	119,000
Australia	2	3,950	474,000
France	6	3,330	56,200
Gabon	1	1,500	18,700

Figures for uranium production are as at June 1983, from estimates made by the Australian Atomic Energy Commission. Reserves are "reasonably assured resources" for 1983 based on a cost range to US\$80 per kg. Values for other countries other than Australia from OECD. No estimates are available for the Soviet Union, Eastern Europe and China.

Defence research

Marshalling scant resources

THE largest research and development complex in the Southern Hemisphere sits some 24km outside Adelaide. It has a staff of 2,660, five square kilometres of grounds, 1,300 buildings and many, many kilometres of high wire fence. It is the main research centre for the Defence Science and Technology Organization (DSTO) and appropriately enough, for those familiar with British military manoeuvres, is just beyond a town called Salisbury Plain.

Besides the Salisbury centre, there are some eight other defence research laboratories around the country, with a total staff of about 4,400, but with fewer research scientists than CSIRO. Annual expenditure runs at \$A140 million or 2.7 per cent of the defence outlay, which is itself 2.7 per cent of gross national product. That is just one-twentieth of the British defence research and development budget, a statistic which explains much of DSTO's character; it seeks to cover the whole range of technical problems even with a very much smaller capability.

Inevitably, most defence equipment is bought abroad rather than developed in Australia and a great deal of DSTO's energy goes into maintaining the ability to give advice on equipment needs as well as adapting foreign equipment to the very different operating conditions of the Southern Hemisphere. Indeed, the spread of knowledge required is such that, occasionally, all the expertise in one area resides in just one individual — to whom it is earnestly hoped that nothing untoward happens.

A little research capacity is, however, left over for the development of quite new concepts. Past successes include Malkara, the world's first wire-guided antitank missile, bought by the British during the Suez War of 1957 when they suddenly realized that they had sold the then impregnable Centurion tanks to the other side. And, after that, there was Ikara, a missile-borne homing torpedo still widely used.

Present public fantasies about DSTO's activities include, if the popular press is a guide, a "death ray" or, more precisely, an electromagnetic rail gun which the United States is said to be keen to see as part of its "star wars" (Strategic Defense Initiative, SDI) inventory. Rail guns fire metal slugs at very high speeds by electromagnetic pulses: one Australian scientist has done some neat work (in the United States) on the power pulses that provide that drive. But there is no major development programme under way and the possibility of involvement with the SDI programme is still a subject of fierce political debate.

There are, however, two big defence projects of worldwide significance. In one, Australia is up with the leaders. The Jindalee over-the-horizon radar system

based at Alice Springs can illuminate an over-the-horizon target by bouncing a high-frequency radar signal off a refracting layer in the ionosphere; the signal will return by the same route, and is picked up by a 2.6-km-long linear array. Clever signal processing is then needed to pick up the target against noise returned from hundreds of square kilometres of background. Essentially, flying objects are detected by their Doppler-shifted signals; ships can be picked up because they are stationary against a background scatter Doppler-shifted by moving waves.

The second project, Winnin, was aimed at building a decoy for Exocet-type anti-ship missiles long before their lethal efficiency was demonstrated in the recent Falklands War. The decoy is now at the "proven concept" stage, awaiting a foreign partner for further development, and was exhibited at the Paris Air Show in May. It consists of a remarkable rocket which can hover, nose up, at any desired height above the ground and which, by a slight tilt, can move from side to side, horizontally. The advantage of using a rocket as a decoy is that it can be launched in just seconds — after an Exocet has been detected, a maximum of two or three minutes are left before impact. The rocket can then hover and move very slowly sideways, just as though it were a ship, so that

the Exocet radar cannot readily tell it is a decoy. To complete the deception, the decoy would carry a sophisticated piece of electronics to amplify and return the missile's radar signal to lure it away from the smaller signal given by the intended target, the ship.

A host of other devices have been developed by the various branches of DSTO. These include the Karinga cluster bomb, the BARRA sonar buoy, and the LADS laser airborne depth sounder which can map 50 km² of ocean an hour with a scanning green laser beam that penetrates to the sea floor. Not everything is designed for purely military use: there is also an airborne neonatal intensive care unit for "flying doctors" and a cheap and tiny parachute which allows water bottles to be dropped from the air without bursting.

Financial pressures on DSTO seem not to have been as great as those affecting CSIRO and the universities. Australia's lack of a large-scale defence industry virtually assures that most research and development must remain within a large government organization, although close links are maintained with such defence industries as exist. Support is given to keep engineering expertise in industry from dispersing between contracts. For the future, the chief problem will be whether the thin skin of experts can be stretched to cover the ever-expanding technology of defence.

Alun Anderson

Australian Institute of Marine Science

Aiming to count starfish

THE Australian Institute of Marine Science (AIMS) at Townsville must be about the only research laboratory in Australia to be reaping some benefit from increasing unemployment. Thanks to the Commonwealth Community Employment Programme, \$A1 million has been found to give 55 people work on a one-year study of the distribution of the Crown-of-Thorns starfish on the Great Barrier Reef.

Other than this welcome inflow of money from a department not normally associated with science funding, AIMS faces much the same problems as other institutes; its budget, currently \$A7.3 million a year, is not rising, but inflation is driving overheads ever upwards. So far this seems not to have dampened the enthusiasm of AIMS's staff who, to the institute's great good fortune, are largely in their thirties and perhaps at the most creative part of their careers.

The institute too is young; it was set up 11 years ago under an act of parliament which gave it responsibility for research in the entire field of marine science and has been handsomely provided with facilities, including three research vessels, the largest of them 24.4 metres long. Uni-

versity researchers speak enviously of "luxurious blue-carpeted halls" (which really do exist), but as the institute is located 50 km out of Townsville, at the end of a 20 km private road, used mainly by hundreds of wallabies, the opportunities for sack and pillage are slight.

Despite the very wide brief AIMS was given, it is not actually able to send scientists very far afield. Research remains firmly linked to the Great Barrier Reef and to the tropical coastline of mangrove forests further to the north.

Current worries are that the reef may once again suffer a massive increase in numbers of the Crown-of-Thorns starfish, similar to that in the late 1960s and early 1970s. The starfish eat the hard-bodied corals, and the result of an outbreak, when starfish can be seen on a reef by their hundreds of thousands, is a change from 45 per cent coral cover to just two or three per cent, with accompanying catastrophic changes in the rest of the reef community.

That the starfish are once again on the increase is suggested by reef surveys and by questionnaires returned to the Great Barrier Reef Marine Park Authority by vacationing skin divers. For AIMS, however, what is most certain about the

outbreak is the vast uncertainty. Nobody knows the true extent, or the dynamics, of the changes in the starfish population, hence the Department of Employment programme, funded to provide a one-year "snapshot" of the coral-starfish system. Two hundred and twenty eight types scattered along the whole length of the reef are to be sampled.

So far at least it does not seem as if the reef is heading for destruction. Areas known to have been decimated 10–15 years ago appear to have recovered their coral cover, although it is not known if the reef is quite the same as it was before. It is entirely possible that outbreaks of the starfish are "natural" and have been continuing for vast spans of time. Cyclic changes in starfish abundance with complex dynamics can be driven simply by predator/prey interactions, as recent mathematical modelling at AIMS shows. On the other hand, cycles may have been triggered by some external factor. Either way, the possibilities for control seem remote. In Japan, an attempt was made to prevent a Crown-of-Thorns outbreak by removing an astonishing ten million starfish from reefs in the Okinawa region, but without success.

Research on the Crown-of-Thorns starfish is but one (temporarily well funded) part of AIM's activities. Elsewhere, diversity is the name of the game, and AIM's activities well illustrate how basic research can confound the ill-informed among politicians and have consequences of economic and perhaps profound social value.

Why, for example, are coral reefs free from bryozoans, tunicates and so on that are found encrusting nearby piers and pilings? The answer proves very simple. In the clear waters of the reef, the levels of ultraviolet light are simply too high to permit their growth — put a sheet of ultraviolet absorbing Perspex on the surface and they will grow in abundance. (Those who hold the popular misconception that ultraviolet light cannot penetrate far in water should read N.G. Jerlov's 1950 *Nature* paper which shows quite the contrary.) The question then becomes one of why corals are not similarly affected by ultraviolet radiation. The answer proves to be that they contain a natural "sunscreen", a UVB blocking agent. This has now been isolated and seems set to form the basis of a commercial sunscreen, or even a marine plastics and paints additive. Results of the research are being held back from publication until formal patents have been filed; a contract with a chemical company to develop the agent has already been signed. Preliminary announcements were feted by Barry Jones, Minister for Science.

Results with broad economic consequences could also stem from a second study (published in part by *Nature* last August) which began when it was found, contrary to received wisdom, that fluorescent

The Crown-of-Thorns starfish again threatens the Great Barrier Reef.

bands appear in sections cut from long-lived *Porites* corals. The bands, in corals growing on the shore side of the reef, turn out to be caused by fulvic acid leached from soil by water; they thus provide a record of nearby river output, and so of rainfall, which can be dated to within a few weeks by X-ray examination of the annual growth rings of the coral. As massive corals may be many centuries old, they thus contain a long-term record of floods, droughts and river flow — exactly the sort of information that saves huge sums of money in the planning of dams and flood control systems.

As well as showing annual cycles, the bandings record much longer-term patterns of atmospheric pressure. The record in the corals has the potential to push knowledge of Australian meteorological conditions back several centuries. What makes this so important is that the region is critical for the Southern Oscillation, the unpredictable shift in weather conditions which caused both the recent Australian drought and the El Niño phenomenon with its profound economic consequences for South American fisheries and indeed, the whole of the South Pacific region. It is too soon to be sure, but the corals could be the first long-term record on which climate modellers can work.

Alun Anderson

Antarctica

Glaciology still on ice

SEEN from Australia, Antarctica is not a remote land at the uttermost end of the Earth but, rather, the nearest southern neighbour, closer to Sydney than either Singapore or Jakarta. Almost half of the continent — some eight million square kilometres — is claimed by Australia. And, uniquely, Australia's claim is disputed by no other nation.

For the time being territorial claims may matter rather less than does the smooth working of the Antarctic Treaty, which has kept the area demilitarized and unexploited and has, so far, provided a model of international scientific cooperation.

Keeping things this way is very much in the Australian interest. Militarization would expose Australia's southern flank, and changes in the environment could affect Australia's weather. Politicians have thus always stressed the importance of maintaining a visible presence there.

For Professor David Caro, vice-chancellor of Melbourne University, and for seven years chairman of the Antarctic Research Policy Advisory Committee (ARPAC), however, Antarctic visibility should mean only one thing — scientific research. But as things are, it seems there is just enough money to get men there but not enough for them to do very much. As he puts it, there has been a "credibility gap between what territory Australia claimed in the Antarctic and what it did there".

Professor Caro is about to end his chairmanship after seven years of what he calls "butting against a brick wall". But there have been some notable expenditures on the Antarctic effort in that period even though they have often been controversial. Sixty million dollars is being invested over ten years in rebuilding the three stations at Mawson, Casey and Davis — to the accompaniment of criticisms that the new designs are too expensive. As Minister of Science Barry Jones put it, "we have the best buildings in Antarctica, but we do not lead in much else". Building methods are now being reviewed and attempts made to cut costs by modular construction. More worrying is that the massive high-quality heavyweight buildings under construction will tie researchers to those particular locations for ever. A cheaper, less permanent solution might well have been preferable.

Construction should, in any case, speed up now that a five-year charter has been taken on a Norwegian supply ship *Icebird*. The new ship will also help one area where research has expanded and no complaints are heard — marine biology. Also in the "not too bad" category are cosmic-ray and meteorological research, which are continuing because they can be carried out

close to the bases. But it is a different story for glaciology and geology — areas in which Australia was once strong. The glaciology has petered out for lack of the tractors or helicopters to make this work possible.

A further bone of contention is that air strips are not maintained at the bases, so that senior scientists whose time is too limited to allow for the six-week voyage cannot fly to Antarctica. This is ironic as the Soviet Union is able to fly to its bases right in the middle of Australia's claim.

On the government side, the Antarctic Division of the Department of Science points out that overall spending has risen, although it has tended to be true that the government has accepted only the cheapest recommendations from ARPAC. But the government is proud of the political initiatives it has taken in Antarctica. The Convention on the Conservation of Antarctic Marine Living Resources came into force in 1982 largely through Australian efforts and is administered from Hobart. The convention is progressive in that it covers all living organisms in the Antarctic ecosystem. Management guidelines to ensure the ecosystem's stability are worked out by the scientific commission of the convention.

Australia is now active in promoting a similar convention on mineral resources; meetings of the treaty members have been taking place every six months. Progress has been steady, but there are potential problems. The parties to the Antarctic

Treaty consist of the seven original "claimant states", nine "full consultative" parties who have paid the heavy entry fee by setting up research facilities in the Antarctic and a further 16 "non-consultative signatories" who enjoy observer status at treaty meetings. Now the whole system has recently come under attack, particularly from Malaysia, which demands that Antarctica should become the "common heritage of mankind" rather than be run by nations rich enough to set up bases there. But conservation groups are concerned that a deal conducted behind the closed doors of the treaty meetings will permit some form of mineral exploitation, with concomitant risk to the environment; the fact that rich but resource-poor countries such as West Germany and Japan are increasing their Antarctic activity is seen as particularly suspicious.

It is in this climate that ARPAC has, time and time again, pointed out that "if Australia is to have an effective influence in mineral negotiations ... and make a significant contribution to the protection of Antarctica from any adverse effects of mineral exploitation", then it should fund research into the geology and related environmental factors of the Antarctic. So far these pleas have fallen on deaf ears. But there is now talk of setting up a new base, on the sliver of the Australian claim to the west of the Ross Sea, to complement the three sited further to the west.

Alun Anderson

Universities

Accessible but ailing science

THREE types of scientist can be distinguished in the New Zealand university research community: those who are furious about their current situation, those who profess philosophical resignation and those who are thinking of moving somewhere else. A fourth, and much rarer, species has found contentment in some external source of funds. Such was the impression gained when a group of scientists aired their frustrations at a small meeting at the Victoria University of Wellington. The essential problem is that there is so little money available that those who wish to do experimental science and to publish in international journals feel that the odds are against them.

One person who has decided to move elsewhere is Professor Ian Axford, vice-chancellor of the university. He is to return to a Max Planck Institute and feels deeply pessimistic about New Zealand's situation, particularly for young scientists, whom he describes as "totally demoralized". Conditions are indeed difficult and even British scientists would find them hard to bear. Funds available per student are 30 per cent less than in Britain and student/staff ratios are 50 per cent higher — which means enormous teaching loads.

But the main complaint is the virtual impossibility of buying a large piece of equipment. And as exchange rates fall, things are becoming critical for books and journals too. Wellington University's library is spending \$NZ1.5 million a year on its library out of the \$NZ25–30 million slice of the running grant it gets from the University Grants Committee. The fall in the real value of that money means fewer journals, and fewer delivered by airmail, which puts the rest of the world even further away.

This points to the second big problem — travel opportunities. It is best not to ask a group of New Zealand academics if they feel they have ample opportunities to visit world research centres. Sabbaticals are actually quite generous; leave can be taken just once every three years, and an air fare is provided as far as Perth (in Western Australia) and then an allowance (or pittance) of \$NZ20 a day. The only hope for improvement lies in increasing the number of international conferences being held in Australia. Faced with lack of funds and isolation, it is small wonder that some prefer the philosophic view and look at the advantages in being away from "the international hubbub", the opportunity to

Christchurch University's new campus lies among woodland on the banks of a tributary of the Avon.

sit back and "be highly selective about what you do". But this seems too much like making a virtue of necessity to appeal to the majority.

A dissenting view may also be heard from those who see the role of the universities somewhat differently. Dick Earle, professor of biotechnology at Massey University, says his main objective has been to establish a pool of well-trained graduates who could take biotechnology into industry, and in that he claims to be succeeding. He works closely with the frozen meat industry, but his research is not dull. He is working on the computer modelling of freezing objects with complicated shapes — the problem is one of phase change at a complex moving boundary, for which there is no analytic solution.

Many university researchers have made formal links with industry or the Department of Scientific and Industrial Research. Ten years ago, there was almost no contract work in universities: now engineers most noticeably, but also chemists and physicists, have taken on industrial work, chiefly because of financial pressure.

Underlying all the individual complaints made about the state of the universities is a sense of neglect. It is not just that there are problems, but that university scientists have, as one of them said, "no-one to wing to". Nobody really cares about them; nobody represents them at a level of government close to where decisions are made. Government, anyway, has often been singularly proud of its anti-intellectualism and has enjoyed making Aunt Sallies out of academics. But there are hopes that this will change as a body something like Britain's Science and Engineering Research Council may well emerge in the next year or so.

Within the present framework, there are varied opinions on the prospects for reform. One possibility would be to stop the too-even distribution of funds. A stiff dose of competitive peer review to replace the cosy "three wise men" might concentrate funds where they are needed and so concentrate the minds of those with real ability.

Professor Axford takes a more radical

Paying for the universities

RESPONSIBILITY for university finances rests with the University Grants Committee (UGC), whose main job is to assess the funds required to run the universities and to ensure that they are equitably distributed. Needs are assessed quinquennially and now amount to \$NZ200 million a year.

Division among the universities is determined by a formula related to student numbers, and is given as a block grant which can be spent as the university sees fit. Eighty per cent inevitably goes in salaries, much of the remainder on maintenance. What is left can be distributed to meet research costs. The system guarantees that all researchers are equally provided for in basic supplies, but it cannot provide large sums or expensive pieces of equipment.

To provide for equipment (that is, anything that an individual university cannot afford from its block grant, generally reckoned to be about \$NZ5,000) a separate UGC fund is available. But currently that stands at just \$NZ3 million a year, having just been hiked up from \$NZ1.8 million at the start of this quinquennium. Another \$NZ3 million a year is available for the replacement of equipment, and enough funds are provided to support 80 doctoral students a year. With possible claims on

the equipment money are some 623 "basic" researchers, 600 "applied" university scientists (including engineering, forestry and the like) as well as 314 doctors, dentists and vets.

The money is doled out not by independent peer review but "three wise men", who interview everyone who applies for a grant. Grant applications run at about three times the value of available funds. Mr David Hall, director of UGC, says, "we never really fund anything totally". It is expected that universities will always find some money elsewhere, by collaborating with the DSIR or otherwise.

New Zealand's seven universities are:

- University of Auckland
- University of Waikato (at Hamilton)
- Massey University (at Palmerston North)
- Victoria University of Wellington
- University of Canterbury (at Christchurch)
- University College of Agriculture (at Lincoln, near Christchurch)
- University of Otago (at Dunedin)

Auckland is by far the largest university with nearly 13,000 students. Canterbury, Otago, Wellington and Massey have 6,000–7,500 students each, Waikato slightly fewer than 4,000 and Lincoln 1,750. □

view. He believes that "basic science is withering" and, partly because New Zealand universities are too small, that success may "not be achievable in the existing framework". He proposes a single Institute of Advanced Studies responsible for "all postgraduate teaching and staffed with groups of more than critical size for strength and survival". Those working elsewhere, at what would become the equivalents of university colleges, would have to be given free time for study visits.

Despite all the problems, there remains one aspect of New Zealand universities

that greatly impresses outsiders: entrance to the universities is "open" for those over 21. At Wellington, 40 per cent of the students are over 25: it is not necessary to study full-time and grants are available to those who have not been to university before. Indeed, Wellington's oldest student is 82 and now doing a doctorate in classics after passing both BA and MA courses. As Professor Axford put it, "it is a very civilizing thing, which improves the whole tone of the community and stops intellectual fossilization". More of that might be welcome elsewhere. **Alun Anderson**

Buildings from the last century, now housing university departments, mingle with modern buildings on Auckland's campus. In the background, the science block.

DSIR

Industrial disease

THE Department of Scientific and Industrial Research (DSIR) is the giant among New Zealand's research organizations: it consumes 45 per cent of the government's science budget and contains almost a thousand scientists, backed up by over a thousand technicians and support personnel, working in twenty-four divisions.

Virtually every area of science is covered — from oceanography and ecology to industrial processing and plant diseases — in what must be one of the world's last comprehensive government research bodies. Elsewhere, similar bodies have grown and fragmented; in New Zealand, the small size of the population and available resources has continued to make it essential to concentrate researchers in a few organizations so that there is some chance for them to reach a "critical mass" for efficient research.

Now, like equivalent organizations elsewhere, DSIR is under pressure to move closer to industry and to recover an ever-increasing part of its costs from the end-user. In 1985–86 its budget was to have been \$NZ97 million, and it will actually be \$NZ95 million; in the succeeding years it will fall to \$NZ90 million and then \$NZ82 million.

The director-general of DSIR, Jim Ellis, interviewed before these figures were announced but clearly having a good idea of what was coming, professed no pessimism about the future, however. At present, \$NZ13 million a year is raised from services, giving the DSIR a true budget of \$NZ110 million, and he believes that there are still hitherto sacrosanct areas, particularly in agriculture, where it would be fair to expect a bigger return from services.

Others within the DSIR divisions (see below) are very much more troubled about the effect the government cut-backs may have. Some too are much concerned about the increasing pressure to do research with short-term benefits. Jim Ellis himself characterizes a good half of DSIR's work as "very mundane, taking in the washing for a lot of government departments that don't have scientific facilities". That even extends to analysing alcohol levels in blood samples for the police. The rest is "long-term strategic research" intended to have application at some time in the future, plus cooperating on joint projects with industry.

But visits to DSIR research laboratories suggest it is not quite as simple as that. Anywhere you go will reveal lots of long-term, basic research going on, much of it no different from what would be found in a university, but rather well concealed behind the camouflage of an applied project. The strange thing is that it often

DSIR consists of three main groups, each containing numerous divisions:

Primary production group

Applied Biochemistry
Crop Research Division
Entomology Division
Grasslands Division
Horticulture and Processing Division
Plant Diseases Division
Plant Physiology Division

Resources group

Botany Division
Ecology Division
New Zealand Geological Survey
Geophysics Division
New Zealand Oceanographic Institute
Science Information Division
Soil Bureau

Industrial Group

Applied Mathematics Division
Auckland Industrial Development Division
Chemistry Division
Christchurch Industrial Development Division
Industrial Processing Division
Institute of Nuclear Science
Physics and Engineering Laboratory
Wheat Research Institute
Information Technology Division

Separately administered are:

Antarctic Division
Geothermal Research Centre, Wairakei

looks as though it is the basic work that will, in the long-term, be much the more valuable.

Jim Ellis is also quite aware that lurking within DSIR are all sorts of odd characters with ideas of their own — and he is very proud of some of them. One story he tells is of the world's first natural gas-to-gasoline conversion plant, being built in New Zealand. A by-product of the xelolite conversion is a polycyclic aromatic called druedurene — which is a real nuisance because it crystallizes in carburettors and blocks them up. But now, thanks to one eccentric's work, it has been discovered

that druedurene can be turned into a high-impact strength polyimide plastic.

New Zealanders clearly value their individuality and around the labs one is often impressed by a neat solution someone has found to a problem — but usually to a rather small problem. In the DSIR's Physics and Engineering Laboratory (PEL), for example, a very neat little laser interferometer machine had been built that can automatically calibrate surveyors' staves at great speed. Much imaginative thought has gone into the work, but the gains might be greater if the same people were to be let loose on something bigger.

Another oddity perceived on a whistle-stop tour is that people are often quite unaware of the activities of other divisions — even when they are concerned with related disciplines. This is particularly curious in a country that is almost small enough for everyone to know one another and perhaps a result of the natural tendency of New Zealanders to be happier left to go their own way. But one gets the impression that for any given problem it could be quite hard to find just the right sort of person to help you. DSIR is certainly aware of this and with the Science Information Profile Systems (SIPS) being installed on the DSIR computer network is trying to remedy it. It will be possible to call up information on any number of staff or to find relevant personnel through keyword entries.

These information activities accompany a recent surge of activity in publishing glossy information pamphlets and advisory manuals for industry. Maybe before long they will be forced to stop telling the famous joke about DSIR: "What's the best way to run a small business? Buy a big one and ask the DSIR for advice".

Alun Anderson

Forestry's fears

A MASSIVE transformation lies ahead for New Zealand's forest industry. At its heart is *Pinus radiatus*, introduced a century ago from California, where it is known as Monterey pine, but which grows phenomenally well in New Zealand. Planting is now at such a pace that, early next century, exports of forest products will probably have increased seven-fold, making forestry a major economic force.

The difficulties involved in this transformation occupy the minds of the 300 scientists and technicians of the Forest Research Institute (FRI), the research arm of the Forest Service. The switch to radiata pine is not the only change. Logging of indigenous forest has been virtually halted and the seven million hectares remaining must now be managed for recreation or as "protection" forest to prevent soil erosion or flooding. Just what the effects may be in a country prone to floods and landslides is one of FRI's problems.

The radiata pine is the most immediate challenge. Harvesting will be done in quite new kinds of areas, while the wood is of an unfamiliar type. Silvicultural regimes, which have a profound effect on wood quality, will have to be worked out by computer modelling of tree growth. New mechanical winches will be needed, while there are unknown dangers from pests. The quality of the wood means that new methods of cutting and processing must be developed. And so on.

FRI is facing these new challenges with enthusiasm but worries that the long-term research required in forestry will be hit by the demands of the government for short-term returns, despite the potential of the industry. Vital experiments on, say, how forests affect water resources and slope stability cannot be turned off and on, nor is there any end-user, other than government, to pay for them.

Yet FRI is better off than the universities, which FRI director Colin O'Loughlin describes as "poorly funded and getting worse". A serious problem, he says, is that "the anticipated expansion of forestry is not being catered for by the universities". So FRI must send people abroad for PhD training for lack of appropriate facilities in New Zealand.

Alun Anderson

Geology and geophysics

DSIR in the research field

GOD (or the gods that control earthquakes) perhaps sometimes works in favour of man. In 1855, just 15 years after Wellington was settled, New Zealand's mightiest earthquake on record tilted a block of land 30 miles wide and 120 miles long, lifting the shoreline at Wellington some five feet. The result was a nice level stretch of dry raised beach all along the coast. And that, local legend has it, allowed a fortune to be made by a settler who had been contracted to build a road along the shore and now found his work largely done.

The road, running just a few feet above the sea, now conveniently links Wellington, where DSIR's Geophysics Division has its headquarters, to Lower Hutt where the Geological Survey is located. Neither institute attempts the hopeless task of predicting earthquakes, which continue at an average rate of a magnitude 7 quake once in ten years and one of magnitude 8 once a

century. The Geophysics Division does, however, offer "words of wisdom and comfort", as one researcher put it, to a public worried about earthquakes and, more important, carries out seismic surveys at construction sites like dams so that, should the thing fall down, the contractor can at least wave the DSIR survey at the court of inquiry.

Accurate seismic risk evaluation, of course, depends upon good records and statistics of earthquake occurrence, and these the division has amassed in abundance. Sophisticated microprocessor-based monitoring systems have also been developed and will help automation of seismic networks. The division also maintains seismic stations in the South Pacific which forms part of the ocean's tsunami warning system. Altogether the division contains 35 scientists, backed up by an equal number of support staff, whose research covers the whole range of the Earth's natural

dynamic activity. Much mapping has been done, including gravity mapping of the whole country, with an eye to the exploitation of natural resources of coal, minerals, oil and geothermal water. Parts of the survey services can be turned to a profit as can the hiring out of seismograph equipment to oil companies. This in turn helps areas such as volcanology that have nothing to offer industry. The pressure to recover more funds from industry sometimes places geophysics in an odd position: if a construction engineer wants to look at seismic records to help design a

safe structure should he be charged — if so, how much?

The Treasury desire that scientists should be looking for customers for their services also looks strange at the Geological Survey. The geology of New Zealand is extraordinarily complicated and the best way to understand it is through fundamental research. Trying to find out only things that someone might want to use would make progress impossible, nor would geological consultants appreciate it much if government geologists really began to compete with them for business!

The survey's 85 scientists perform the primary function of mapping as well as a range of research projects in petrology, palaeontology, Earth deformation and engineering geology. A major study is running on the Cretaceous and Cenozoic sedimentary rocks of the region, principally because they contain all the known coal and petroleum reserves. Most of the

basins of interest are offshore but the lack of an ocean survey vessel is not a problem — all the companies (mainly big foreign oil companies carrying out commercial survey in the region) are required to deposit data, cores and samples, and seismic tapes with the government. These came geology's way because the survey sells its services to the Ministry of Energy who need expert comment on applications for exploration licences.

Much of the expertise acquired in dealing with the petroleum industry is being passed on to smaller countries in the Pacific region. An invitation-only meeting has just been held on "Government and the petroleum industry" to advise representative geologists from the Pacific islands what to do when exploration companies come looking at the sedimentary basins, containing potential oil reserves, that some of the islands possess.

Alun Anderson

New Zealand's changing agriculture

A GLANCE at the histograms below will tell you that New Zealand's agriculture, responsible for some 80 per cent of export earnings, is in a period of transition. The traditional money earner — the export of meat — is scarcely growing at all.

Intelligent diversification in the dairy industry has maintained some growth, and the demand for wool too is "holding up". But real growth is only being seen in fish, helped by the creation of the 200-mile protection zone; wood products, which are just at the beginning of a big leap forward; and horticulture, powered by the amazing success of kiwi fruit.

Just what has happened to New Zealand's traditional exports became clear from conversation with Pat Joyce, looking out from the roof of the Ruakura Agricultural Research Centre, Hamilton, over the acres of experimental land he is responsible for. In quite a few of those acres, deer are grazing in pens. An eager export market has been found for venison and the breed is being improved. Indeed, hunters who used to shoot wild deer from helicopters now bring them back alive for breeding.

The move to deer (along with angora and mohair goats) has come about because of the increasing difficulties of exporting the traditional products of sheep and beef. Most countries have quotas for beef now and, in what could be a big market for sheep, the United States, the Sheep Growers' Association form a powerful lobby. The traditional UK market was, of course, lost after Britain's entry into the European Economic Community.

With these changes comes an ever increasing need for research, firstly to exploit the new opportunities seen in the rapidly growing non-traditional product areas, and secondly to do something about the static areas. Despite the kiwi fruit

miracle, horticulture is not about to replace meat as the main export and new markets have to be found for the traditional products. Already there is much dependence on less-than-stable countries. Half of New Zealand's lamb now goes to Iran. China is taking a large part of the wool exports. But to break into the big US markets, changes have to be made — lamb, for example, would have to be made acceptable for TV dinners. At the same time, new spin-off products — such as adv-

anced milking machines — have to be sold overseas.

These demands come just as the government has announced that the 1985–86 budget for Ministry of Agriculture and Fisheries research is to be cut to \$NZ67 million from an expected \$NZ68 million; the next year it will fall to \$NZ63 million, and then to \$NZ58 million. The shortfall is to be recovered from industry by contract work and charitable services, such as soil analysis. This leaves places like Ruakura with a bit of a problem for they know, even if the Treasury does not, how vital it is to keep the long-term research projects going.

Alun Anderson

Information technology

DSIR in the picture

If all DSIR's scientists were put together they would not match the resources of even one big US or Japanese electronics manufacturer. What opportunities are there then for DSIR's newest division — that for information technology — set up, one hopes inappropriately, on April Fool's Day this year with just 20 scientific staff?

Surprisingly, the answer is "plenty", for the new division is finding a niche appropriate to its size. It has already equipped itself with glossy brochures from a software company that is selling an image analysis package developed by division scientists. And if the enthusiasm of its young director, Peter Ellis, continues to win over the government, New Zealand will soon have a chance to get in on the potentially lucrative satellite image processing market.

The image analysis package, called EPIC, is a flexible system for enhancing digitalized images — it can be used to deblur images, colour different image values, remove distortions, interpolate values and the like. There are a thousand and one uses for such packages, from intensifying details in X-ray images to picking out the number plate of a speeding motorist caught with a video camera.

But what particularly interests the new division is satellite image processing. Much of their expertise was gained in working on Landsat images (bought on large magnetic tapes) and their hope — inspired by some nods from the government — is that a ground station will be built to receive real-time images from SPOT, the French resources satellite to be launched later this year. Later on, other satellites could be tapped — the European Space Agency's ERS-I and then the two Japanese marine observation satellites. Use of SPOT would allow very fine mapping to be carried out as well as real-time crop analysis. Beyond that, if all goes well, there are even ambitions to participate in the design of instruments for use on-board spacecraft.

Most of the division's work is more down to earth. Major effort goes into running the DSIR's computer network and ensuring that the best software is available: here it is careful monitoring of what is available around the world rather than expenditure of original research that counts.

Image processing and the network between them absorb nearly all of the division's resources: what is left goes into projects such as a computerized system for the government printer, and character recognition systems to help with archiving in the National Library.

Alun Anderson

Advisory Council

A watchdog with no teeth

JUST as messengers carrying bad news run the risk of being blamed for the news itself, so central organizations for giving advice on science run the risk of being unpopular when finances are being cut.

New Zealand's National Research Advisory Council (NRAC) is no exception to this rule.

Nobody, it seems, has a good word for the council. The most charitable comment is that "NRAC is not what we need, but it's really not their fault". Indeed, if NRAC's recent record is anything to go by, it has laboured mightily with limited resources to advise a government which has little intention of listening. That may change, for NRAC is likely to be reborn in a new form. Almost nobody doubts that some such body is needed, and badly.

NRAC was set up in 1963 to give advice on the planning of scientific research, including the setting of priorities for government departments. Three kinds of obstacles have, according to government critics, made it impossible for NRAC to fulfil this role. First, the organization is very small (12 committee members) and relies on busy people, with commitments elsewhere, who cannot deal with the multitude of tasks that come their way. Second, it has never had a professional technical secretariat, but has to beg, borrow and steal personnel from the Department of Scientific and Industrial Research (DSIR) and other bodies. And finally, the government has tended to ignore it.

The line of communication to government is certainly long: NRAC reports to the Minister of Science (a low-ranking portfolio), who then reports to the cabinet, rather than directly to the Prime Minister. And again, the minister's portfolio includes responsibility for DSIR, so there is a confusion of his role as an overseer of the whole of science and as a director of one major science body.

To point out that there are shortcomings in the system is to say nothing new. NRAC's role has been under some kind of review for four years; self-criticism has been rife for longer. In July last year, the Probine report on the means by which the government obtains advice on science and technology policies recommended that NRAC should be revamped as a Science and Technology Council which, like those of other countries, would report directly to the Prime Minister. That report also asked for a new research council, with funds independent of those of the UGC, which could harness "under-utilized talent and equipment in the universities".

No action has yet been taken; NRAC is left "hanging in the air" as one member puts it, although action of some sort is still expected.

Uncertainty and criticism there may be, but NRAC has not been inactive. Its 1984

"Science and Technology Plan" surveyed the whole of New Zealand's research effort, and has not escaped criticism. Those involved in applied research say that it states the obvious, while those in the universities are offended that "The role of the universities" occupies a mere two of 166 pages. But the report was intended to be "more of a review than a plan"; a second plan is to appear shortly and seems considerably more vigorous.

To compile the 1985 plan, the "users" of science (manufacturers and primary producers) were approached to discover their needs; merely making this effort seems to have awakened considerable interest among the producers. Scientists also had an opportunity to air their views at a large May conference on "Science and Technology for Development", which generated several inches of documents from indus-

trialists, technologists and academics on the remedies for New Zealand's woes. No panaceas or plans for radical reform emerged, but plenty of heated argument.

The head of NRAC, Alan Mackney, is not averse to expressing a few strong opinions either. On the government's attempts to recover a fixed percentage of funds by the user-pays principle, he says that "an arbitrary amount to be got without rhyme or reason" just does not work", and that if the user, who often does not know what he needs, is to decide what must be done, New Zealand will be "frozen into pre-technology".

The annual reports of NRAC, too, contain endless recommendations that science should be taken more seriously. But until NRAC is reborn as a body that represents all scientists and technologists (and the universities have been conspicuous by their absence) and until it has real teeth (access to decision-makers and money), its activities will continue to be all bark and no bite.

Alun Anderson

Geothermal energy

Looking for a crock of gold

NEW Zealand can proudly point to one area of research where it is a world leader: the chemistry and physics of geothermal systems. Confounding the politicians who are now demanding a short-term pay off from science, the long-term accumulation of expertise in geothermal research has allowed two New Zealand consulting firms to win big foreign contracts for the design of geothermal power plants. In 1958, New Zealand became the first country in the world to build a geothermal power plant operating on the mixture of steam and hot water that is found in the vast majority of the world's geothermal fields. Part of the steam was originally intended for a UK heavy-water project never carried through. Fortunately, the flexibility of the design for turbine operation has meant that the power plant, at Wairakei, is still operating with utter reliability producing 5 per cent (160 MW) of the country's electricity.

To generate the electricity, one tonne of fluid a second is taken from boreholes drilled one to two kilometres into the ground. The area has become a mecca of geothermal understanding. There have been some surprises. As steam has been taken out of the ground, the water table has fallen as much as 15km away, and the surface has subsided, in one place by 0.4m a year. A nearby tourist attraction that used to be called Geyser Valley is now known as Geothermal Valley because the geysers have turned into mud pools. On top of that, an unhealthy level of arsenic has been found in the geothermal water discharged into the river that flows down to the town of Hamilton.

None of these problems has proved as serious as might appear, however, while the expertise gained and the basic research done on the geothermal system have paid dividends. Now two geothermal companies, GENZL and KRTA, contain-

An active geothermal field in central New Zealand.

ing many researchers formerly with the Department of Scientific and Industrial Research and the Ministry of Works, have taken a large share of contracts in the Philippines, which is now second only to the United States in the number of its geothermal power plants.

The latest surprise at the Geothermal Research Institute has been for the geochemists: the insides of some of the borehole pipes have been found to be coated with gold. What seems to be happening is that, in the geothermal system, gold forms a complex with dissolved hydrogen sulphide which precipitates when the pressure drops. The implications are important. Hitherto the amount of gold deep in the system has been inferred from that left in the geothermal water, but with the amount now known to be deposited added to that, it seems that, deep down, the hydrothermal water is close to saturated with gold. This strengthens the case for thinking that the geothermal system beneath Wairakei is a living model of fossil geothermal systems that are now being actively mined for gold and study could thus aid prospectors. The work on gold deposition is not yet published, but Richard Henley's book *Fluid-Mineral Equilibria in Hydrothermal Systems* is already a modest bestseller, going into a second printing after nine months.

Capable of supplying 5 per cent of New Zealand's electricity, the Wairakei geothermal power plant.

While prospecting for gold may be in fashion, prospecting for steam is in the doldrums in New Zealand. The black art of prospecting has been refined by the Wairakei centre so that the chances of a

borehole turning out to be successful are very high indeed. The technique is a combined operation between geologists, who do the basic mapping, geophysicists, who use electrical resistivity and seismic techniques to map the reservoir, and geochemists who reckon to predict subsurface temperatures from analysis of fumarole steam. (Asking which group contributes most is a sure way to begin a brawl.) But there is little chance that new power plants will be built in New Zealand. Instead, the tricks of the trade are being transferred to others at a special Geothermal Institute, supported by the United Nations, at Auckland University.

Just why New Zealand has been able to keep the lead in this area was neatly explained by Jeff Hedenquist, a geochemist at Wairakei, and himself from the United States. In New Zealand, all geothermal work is done by government agencies and information is freely available; in the United States, by contrast, there is free competition for contracts which sometimes means that one system is drilled by several companies without any sharing of information. The result is that it may be difficult to understand the system as a whole. Perhaps the New Zealand government should bear this in mind before pushing ahead with its plans for "liberalization".

Alun Anderson

Chinese gooseberries and tree tomatoes lead the way

"It's a miracle", said one Australian agriculturalist, "that the New Zealanders have been able to sell that horrible looking, tasteless fruit". He was uncharitably referring to the kiwi fruit, a few years ago totally unknown and now on supermarket shelves from Tokyo to London, this year worth \$NZ220 million in export sales.

The curious thing about the kiwi fruit is that it really has nothing at all to do with New Zealand. Its first mention is in a poem written in the Tang dynasty: the kiwi fruit is Chinese, and came to New Zealand only by chance. At the turn of the century, in Yiohong, on the Yangtze River, a small colony of missionaries and traders learned to cultivate the fruit as a local novelty. Among the missionaries were three young Church of Scotland ladies from New Zealand. One of them had an adventurous sister who came out to China for a holiday, and took back with her seeds of the "Chinese gooseberry" which she passed on to a local sheep farmer with an interest in novel plants. All the kiwi plants in New Zealand can be traced back to these first specimens.

As the Chinese gooseberry, the plant was never a commercial success. Turners and Growers, New Zealand's best known fruit merchants, tried to sell it in California without success. At a meeting called to remedy matters the chairman of the board, in a moment of inspiration, rejected a suggestion that the fruit be renamed the

"melonette" and pronounced, "this is the land of the kiwi and it shall be the kiwi fruit". The rest is history. Exports have grown from \$NZ4 million in 1976 to \$NZ220 million this year. From the number of kiwi fruit plants now going into the ground, it is predicted that by 1990, the industry will be worth \$NZ740 million. If that happens, horticulture will account for 13 per cent of New Zealand's exports com-

It's from the U.S. Navy—can we sell the idea of nuclear warships?

pared with 5 per cent now and just 2 per cent five years ago.

So Rod Bielecki, director of the DSIR Division of Horticulture and Processing, wonders if the government knows exactly what it is doing. The Treasury is squeezing research funds and demanding that more money be recovered from industry, just as

an important new export sector is being born. Behind the kiwi come a host of other exotic fruits being readied for the export market: fijoas, tamarillos (no longer called "tree tomatoes"), persimmons, Asian pears and pepinos, already not uncommon in Tokyo supermarkets.

To make them into real winners, there will have to be selection programmes to improve taste, cultivars specially suited for New Zealand conditions, research on plant pests and on the improvement of keeping qualities. Bielecki feels the government is far too keen to transfer the burden of research to industry when, if anything, increased government research in this sector would pay dividends.

To those who say that the money should be recovered from the farmer, Bielecki replies that most horticultural end-users are small single farmers, who need one central research institute. Nor does Bielecki believe the government understands the role science plays in generating wealth. It was one of the division's predecessors which identified kiwi fruit varieties that keep long enough for them to be exportable. More recently, the division was called in when an unexpected frost hit before harvesting was complete, and it seemed that much of the crop might have to be dumped. As fruit growers expand into less favourable land, and as the range of fruits increases, there will be many other problems to solve.

POLYSPECIFIC ANTIBODIES TO MOUSE IMMUNOGLOBULINS

These products are ideal as secondary antibodies in many immunoassay systems using mouse monoclonal primary antibodies. Applications include:

1. Antigen localization in tissue sections, blood cell preparations or cell cultures.
2. Leucocyte identification and counting by flow cytometry.
3. Leucocyte separation by fluorescence cell sorters.
4. Solid phase enzyme immunoassay for monoclonal antibody screening and antigen detection.
5. Affinity isolation or immobilization of monoclonal antibodies on solid phase support media, e.g. affinity chromatography.

FEATURES OF SILENUS ANTI-MOUSE REAGENTS:

1. Well balanced reactivity to all mouse IgG subclasses (1gG1, 1gG2a, 1gG2b, 1gG3), IgM, IgA, kappa and lambda.
2. Cross-reactivity to human and rabbit immunoglobulins has been removed by solid phase immunoadsorption.
3. These products have been extensively tested by and are used routinely at leading Australian clinical and research laboratories employing monoclonal antibody techniques.

ANTI-MOUSE IMMUNOGLOBULIN (RAISED IN SHEEP)

Grade	Code
Stabilized antiserum	DS
IgG fraction of antiserum	DC
IgG fraction, FITC conjugated	DF
IgG fraction, TRITC conjugated	DR
Affinity isolated	DA
Affinity isolated, FITC conjugated	DAF
Affinity isolated, HRP conjugated	DAH
F(ab') ₂ fragment	DD
F(ab') ₂ fragment, FITC conjugated	DDF
F(ab') ₂ fragment, TRITC conjugated	DDR
F(ab') ₂ fragment, affinity isolated, FITC conjugated	DDAF

* We produce a wide range of quality antisera to human and animal proteins. Please contact us for your copy of our new immunodiagnostic reagents catalogue and details of your local distributor.

THE DEVELOPMENT OF A MEDICINE

R. B. SMITH

A highly readable account of an area which is of vital interest to the medical profession and the public alike.

The Development of a Medicine places the discovery and development of medicines in a historical context and then explains the extremely complex and lengthy process by which a drug or medicine is developed from the laboratory bench to availability for prescription by the physician.

After twenty years' research and clinical work in medicine and pharmacology, R. B. Smith is now a consultant to the pharmaceutical industry.

Biotechnology Australia Pty. Ltd.

- ☆ Biotechnology Australia is Australia's largest biotechnology research company.
- ☆ Employs over 100 staff of whom 30 are PhD's.
- ☆ Research is carried out in own laboratories and pilot plant.
- ☆ Fermentation capacity up to 3000 litres, state-of-the-art equipment.
- ☆ Research in the area of recombinant DNA, protein chemistry, immunology and entomology.
- ☆ The main commercial areas for products will be: Animal Health and Production, Human Health, Diagnostics, Biological Pest Control and Mineral Leaching.
- ☆ Products already developed include:
Fully recombinant vaccines against scours in pigs and calves
Murine Interleukin 3
Bioinsecticidal preparation of nematodes
High resolution ELISA microtitre plates

Stefan Marinov wins friends

The suggestion that there are systematic departures from the strict requirements of special relativity has been persistently put forward by Dr Stefan Marinov. There is a case for repeating his experiment.

STEFAN Marinov is a remarkable iconoclast who is convinced that Einstein's special theory of relativity is mistaken. Bulgarian by origin, Marinov has been, for all practical purposes, exiled from his homeland, but it is by no means clear whether his opinions on relativity or on the proper conduct of the Soviet leadership are chiefly responsible.

From his new home in neutral Austria, Marinov has been at loggerheads with several scientific journals, *Nature* among them, because of their refusal to publish any but a small part of his work, which now also includes a purported demonstration of a *perpetuum mobile*.

Marinov's frustrations with the journals have recently seemed to get the better of his judgement. Last year, angered by *Nature's* refusal to publish a group of manuscripts, Marinov was for a time threatening to immolate himself in the square outside the British consulate at Genoa. Later, he threatened to do the same outside the British embassy in Vienna, but fortunately settled for a press conference instead. Those who have had dealings with Dr Marinov can have been left in little doubt that he is passionately convinced of the correctness of his position on special relativity. Quite apart from his apparent willingness to take his own life, it is clear that his waking hours are almost all spent in correspondence, much of it unfortunately fruitless, about this theory and about his purported demonstration, by means of what he calls the "coupled-shutters experiment", that the velocity of light is not, as Einstein's theory supposes that it would be, equal in all directions (isotropic) in all frames of reference.

Now, it seems, Marinov has won some influential friends. The issue of *Physical Review Letters* for 8 July (55, 143; 1985) contains an article by A.K. Maciel and J. Tiomno from the Brazilian National Science and Technology Research Council at Rio de Janeiro which at least puts Marinov's objections to special relativity in a context in which they can be grappled with. Moreover, what Maciel and Tiomno say is certain to have an important bearing on the classification of all possible experimental tests of special relativity.

Plainly, when there is such a mountain of experimental evidence that the general features of special relativity are borne out in practice, it would be foolish in the extreme to assert that special relativity is just plain wrong, thereby implying that the

time has come to return to newtonian mechanics; after all, objects do not travel faster than light in any circumstances observable, while time dilation (as defined by Lorentz) is a fact of life and can be measured, for example, by the difference between the average lifetime of an unstable particle in motion and at rest. So if there are violations of special relativity, they are at most weak violations, departures from what is not strict orthodoxy and not flat contradictions of it.

But what weak violations of special relativity are neither trivial nor absurd? Borrowing from some work due to H.B. Ives in the 1930s, Maciel and Tiomno argue that it is prudent to disallow violations for electromagnetism, for independent particles in uniform motion and the other more elementary phenomena used as illustrations of special relativity, now even in the elementary textbooks. But what about the possibility that the behaviour of rigid bodies is not accurately accounted for by the Einstein-Lorentz transformations of coordinates, and that a rigid body remains rigid — the separation of fixed points remains constant — however it is moving?

The formal realization of this state of affairs seems not particularly elusive, although it is not possible to modify special relativity in any meaningful way without reintroducing the newtonian concept of absolute time and space, or the idea that there may be some preferred frame of reference such as that of the microwave background. Explicitly, if x, y and z are cartesian coordinates in that absolute frame of reference, and t is the time, and if primed quantities are the same coordinates in a system moving at velocity v along the x -axis, the transformed coordinates are exactly those of special relativity except for t' , which is given (according to the formalism of Maciel and Tiomno) by $t = \gamma t'$, where $\gamma = (1 - v^2/c^2)^{-1/2}$ and not the conventional Lorentz transformation in which xv/c^2 is added to t' .

The calculations are not in themselves particularly difficult. It emerges simply enough that rigid rotating bodies remain rigid in the new system, and in the particular sense that the apparent angular velocity of all fixed points is a constant (if the angular velocity of the whole object is constant). The velocity of light is isotropic in the absolute system against whose coordinates the rotation of the rigid object is defined, while both time dilation and

the Lorentz-Fitzgerald contraction (of lengths in the direction of relative motion) persist. What is sacrificed is the isotropy of the velocity of light in the rotating system.

The interest of what Maciel and Tiomno have done is that they can sort the several published tests of special relativity by the likelihood that they will yield a stringent test of the weakly violated form of special relativity defined by their transformation. The classical test of special relativity first carried out by Michelson and Morley and since repeated several times does not meet the test. The version of the experiment due to Joos (published in 1930) in which a Michelson interferometer was rotated on its turntable once every ten minutes or so, classically one of the better verifications of the isotropy of the velocity of light (among two orthogonal directions), will not suffice, although a more rapidly rotating turntable might meet the need. The simulation of the Michelson-Morley experiment in which two hydrogen masers are used as the source of radiation moving in orthogonal directions offers more hope of providing a stringent test of the modified transformation equations. And so, Maciel and Tiomno say, does Marinov's rotating-shutters experiment.

The principle of that is simple enough, a kind of Fizeau measurement of the velocity of light except that the objective is to make a direct comparison of the velocity of light in two opposite directions. Two disks with identical perforations are mounted parallel to each other at opposite ends of an axle and light from a laser is directed (by means of a beam-splitter) through the perforations of the disks in each direction. Marinov claims that his results, most recently obtained with home-made equipment at Graz, demonstrate that the velocity of light is not the same in all directions. He even claims to have been able to detect the velocity and direction of the Earth's movement through absolute space and time.

None of this proves that there is anything wrong with special relativity. It is merely a pointer to the kinds of tests that would be necessary to demonstrate a particular (and "weak") violation thereof. Maciel and Tiomno merely say of the Marinov experiment (as of the others on their list) that it "should be repeated even if to prove it wrong". It will be interesting to see how many correspondents write in to claim that that has been done already.

John Maddox

Haemoglobin structure

A clam with a difference

from Max Perutz

ALL vertebrate haemoglobins are tetramers made up of two pairs of unlike polypeptide chains, termed alpha and beta, each chain forming a basket for one haem. But on page 227 of this issue W. E. Royer Jr, W. E. Love and F. F. Fenderson demonstrate that haemoglobin of the clam *Scapharca inaequalis* has a quite different form of subunit assembly.

In vertebrate haemoglobins, the alpha chain is coiled into seven helical and six non-helical segments, and the beta-chain is coiled into eight helical and six non-helical segments. The tertiary structures of both the alpha and beta chains are similar to each other and to myoglobin, and the residues lining the haem pockets are largely homologous. The vertebrate tetramer has pseudo-tetrahedral symmetry with one true dyad axis running through a central water-filled cavity and two pseudo dyads at right angles to each other and to the true dyad. Assembly occurs in two stages: first, one alpha and one beta chains form a tightly bound dimer; and second, two such dimers combine to form a tetramer. The allosteric change between deoxyhaemoglobin and oxyhaemoglobin consists in a large rotation and slight translation of the two alpha-beta dimers relative to each other.

The haemoglobins of two primitive vertebrates, lampreys and lungfish, are monomeric when oxygenated and oligomeric when deoxygenated; the monomer has a tertiary structure similar to myoglobin. The same is true for all the invertebrate haemoglobins whose structure has been determined and for the haemoglobin found in the root nodules of leguminous plants, suggesting that the myoglobin fold is a universal pattern (see figure) that has evolved to provide the surround for an oxygen-carrying haem.

A suspicion that the quaternary structure of invertebrate haemoglobins may be different from that of vertebrates arose from the observation that one of the larval haemoglobins (component X) of the fly *Chironomus thummi thummi* has a marked Bohr effect coupled to a dimeric structure at pH 5.5 and to a monomeric structure at pH 7.0. Bohr effects probably arise from the ionization of histidines, but no histidine in this haemoglobin is at a position corresponding to subunit contacts in vertebrate haemoglobins.

Royer *et al.* now show that haemoglobin of the blood clam *S. inaequalis* has a tertiary structure similar to myoglobin, but with one additional helix at the amino end which lies parallel to the carboxy-terminal helix H and brings the terminal amino group close to the terminal carboxy group. It is in its quaternary structure that

the clam haemoglobin is exceptional. Two like monomers assemble to form dimers, not by contact between helices G and H as in vertebrates, but by contact between the

The universal tertiary structure of, from left to right, sperm-whale myoglobin, horse haemoglobin alpha chains, horse haemoglobin beta chain and haemoglobin of the clam *Glycyca dibranchiata*. In each picture the amino end is on the left.

haem-linked helices E and F, so that the haem pockets lie on the inside of the tetramer, as Pauling once imagined, rather than on the outside, as in vertebrates. Two chemically different dimers join to form a tetramer; as far as one can make out from Fig. 2 of Royer *et al.*, the tetramer is formed by contact

between helices A, and between the non-helical segments NA and GH. The dyad axes of each of the individual dimers make angles of 75° with the dyad joining the two dimers, so that there is no tetrahedral symmetry.

The structure solved is that of the carbonmonoxy-derivative which is probably isomorphous with the oxy-derivative. Oxygen binding is cooperative with a Hills coefficient of 2.1, and loss of

oxygen is linked with polymerization of the tetramer. It will be interesting to see if solution of the deoxy-structure reveals the mechanism that triggers this polymerization. □

Max Perutz is at the Laboratory of Molecular Biology, MRC Centre, University Medical School, Hills Road, Cambridge CB2 2QH, UK.

X-ray astronomy

A new breed of oscillator

from N. E. White

THE first short timescale periodic oscillations from a bright galactic centre X-ray source (GX5-1) are reported by van der Klis *et al.* on page 225 of this issue. These quasi-periodic oscillations (QPOs) probably indicate the presence of an accreting neutron star that is rotating with a period of a few milliseconds. This discovery may provide timely support for recent models for the evolution of low-mass X-ray binary stars (LMXBs) into millisecond radio pulsars. Furthermore, the oscillations themselves display intriguing characteristics requiring some ingenuity from theorists seeking to explain them.

An accreting neutron star will only be seen as an X-ray pulsar if its surface magnetic-field strength is high enough to tunnel the inflowing material from its companion star onto the magnetic pole. The spin-down properties of radio pulsars suggest that neutron star magnetic fields decay on a timescale of 10^6 – 10^7 years. If neutron stars are born with the same surface field of 10^{12} – 10^{13} Gauss, then those located in the X-ray binaries should show a range of field strengths depending on their age. X-ray pulsars are usually associated with young population I objects (OB stars). In contrast, the older population II

LMXRB systems (where the mass-losing star is of a late spectral type) rarely contain X-ray pulsars.

Any material that flows between components in a binary system must lose angular momentum before it can fall onto a compact object. It may form an accretion disk which will mediate the flow and, by exerting torque, will spin the neutron star up to equilibrium period at which its rotation period is equal to that of the innermost keplerian period of the disk. If a strong magnetic field is present this is determined by the radius at which the magnetic pressure disrupts the disk; for a typical X-ray pulsar with a field of $\sim 10^{12}$ Gauss the equilibrium period is a few seconds. If the field is less than 10^8 Gauss this disk will extend to the neutron star surface and the equilibrium period is ~ 1 ms. It takes only 10^6 – 10^7 years to spin a neutron star up to this period.

This scenario has encouraged the search for millisecond periodicities from LMXRBs but with no success until van der Klis *et al.*, using the European Space Agency X-ray observatory (EXOSAT) because it is probably more sensitive to millisecond periodicities than previous X-ray satellites, searched again for milli-

second pulsations from the brightest of the LMXRB — the galactic bulge sources.

The oscillations found from GX5-1 are not at a single frequency but rather show a distribution of frequencies whose centroid and width are correlated with luminosity. An increase in luminosity by a factor of only 1.4 causes the average frequency to increase from 20 to 40 Hertz and the frequency spread to increase from 4 to 12 Hertz.

The large variation in frequency eliminates the possibility that QPOs directly reflect the spin period of a neutron star. Any model must explain the very strong dependence of oscillation frequency with luminosity. Of the various possibilities discussed to date, the most promising seems to be an instability at the edge of a magnetosphere. Magnetospheric models use the fact that an increase in mass-transfer rate (luminosity) will cause a compression of the magnetosphere such that the characteristic keplerian period at the inner edge of the accretion disk becomes shorter. This gives a frequency/luminosity dependence that is in the correct sense and, with some refinement described elsewhere in this issue², the correct magnitude. These models predict a neutron star rotation period of roughly 10 milliseconds and a surface magnetic field in the order of 10^9 Gauss for GX5-1.

The orbital periods of high-luminosity LMXRBs ($\sim 10^{38}$ erg s⁻¹) such as GX5-1 are in general unknown, but in the two sources where they have been measured, ScoX-1 and CygX-2, are found to be 0.7 and 9 days. In these cases, only an evolved giant companion star can fill its Roche lobe, such that the mass transfer will be driven by the evolutionary expansion of the giant (causing the stars gradually to spiral apart). In such a system the mass transfer ceases when the mass-losing star becomes degenerate.

It has been pointed out that the compact object may begin as a white dwarf, but because of the extra mass accreted, is pushed over the Chandrasekhar limit to collapse into a neutron star³. This could lead to a young X-ray pulsar in an LMXRB. The magnetic field then decays on a timescale that is a factor of ten shorter than the evolutionary timescale. It is plausible that if the neutron star is formed close to the end of the mass-transfer phase then a sizable magnetic field will be left and a millisecond radio pulsar born.

The discovery last year of a 6-millisecond pulsar that has a degenerate companion in a 120-day orbit caused much excitement because such a binary is expected as the end-point of this scenario⁴. The parameters deduced from the magnetosphere model for the underlying neutron star in GX5-1 are similar to those determined for the 6-millisecond radio pulsar. This may be a coincidence — if the 6-millisecond pulsar evolved from a LMXRB it would presumably have looked very like GX5-1 does today.

The magnetosphere model, however, has at least two worrying aspects. First, it is perturbing that the underlying rotation period is not detected. Although there may be ways around this problem (for example, smearing of the pulses in surrounding material) it remains unsolved. Second, the nature of the magnetosphere model allows it to reproduce any frequency/luminosity relation if the dynamic range of the luminosity variation is small. This makes the model extremely flexible, but means that it is not uniquely specified by the data. Other possible models for QPOs are not sufficiently developed to make specific predictions. One suggestion (based on a similar phenomenon that has long been known from the cataclysmic variables) is that the neutron star does not have a substantial magnetosphere, and that the oscillations are generated in the large velocity gradient of

the boundary layer between the disk and the neutron star surface⁵.

Following the GX5-1 result, QPOs have been found in two other low mass X-ray binary stars of high luminosity and long orbital period, ScoX-1 (ref.6) and CygX-2 (ref.7). QPOs had previously been missed in these two sources because observers were searching for single peaks in their power spectra rather than broad humps. □

Archaeology

Industrial revolution in York

from Richard Hodges

RESCUE archaeology has produced a wealth of information about town and country settlements in Britain from Neolithic to modern times¹. These archives constitute a remarkable documentation of our heritage. However, in a phase of stock-taking imposed by current financial constraints it seems appropriate to ask how we have benefited from these excavations.

Most rescue excavations have been concerned with historical archaeology. Redevelopment of inner city centres has allowed deep-stratified excavations of medieval, Anglo-Saxon and Roman layers. The same has happened in the countryside where deep ploughing has obliterated very many remains of Roman-period, Anglo-Saxon and medieval villages and farms. One consequence of this destruction is that there now exists an accurate measure of all these types of historical settlements. The prospects of writing a history based on material remains

has not been fully appreciated until now. To illustrate this point I discuss here some recent excavations which reveal what the written sources do not — the first English industrial revolution.

Rescue excavations reveal the scale of change that occurred in about AD 900. The

Excavations at the Coppergate dig, York. (Courtesy of Jorvik Viking Centre, Coppergate, York YO1 1NT, UK).

Viking dig at Coppergate, York (see figure) provides probably the most perfect illustration of the industrial explosion which occurred at the beginning of the tenth century². Rescue excavations beneath the modern tenements at Coppergate have uncovered a collection of workshops laid out at right angles to the modern street grid. The timbers surviving in these structures are dated by dendrochronology to about AD 900. Much rubbish, associated with the occupation of the associated tenements as well as their workshops, provides some measure of the revolution in craft production in Viking York. As Richard Hall shows³, these tenements were planned on largely unoccupied ground; coopers, moneyers and smiths worked here in the tenth century. Botanical evidence as well as the microscopic remains of beetles and other insects betray the living conditions of the new urban class, whereas excavations elsewhere in the city show a high mortality rate among children and a shorter life-span for women by comparison with rural standards of the age³.

Coppergate, like many smaller rescue excavations in York, confirms the decline of the Roman town in the fourth century, as well as the general desertion of the centre between about AD 400 and 900. The urban take-off, focused on these earlier administrative settlements, occurred in around AD 900, and with it York was transformed. Rescue excavations in Viking towns such as Colchester⁴, Lincoln⁵, Northampton⁶ and Thetford⁷ have documented the transformation from a rural elite centre to a vibrant market town during this period. At Northampton, for example, the middle Saxon minster and the Mercian palace have been located and excavated; both were subsumed into the matrix of a fast-expanding tenth century market⁸. Indeed, the mark of the Viking age in eastern England are these markets and the development of craft production.

New markets are also a prominent feature of most southern English towns at this time. Their foundation may be considered the real achievement of King Alfred the Great. Recent excavations in Canterbury, Chichester, Exeter and London⁹, as well as Martin Biddle's famous excavations in Winchester¹⁰, all conclusively demonstrate that these places had lain more or less vacant since Roman times until they explode into life once more at the end of the ninth century. Most medieval street systems stem from this time. Thousands of tons of gravel were quarried and laid in an operation that was as complex as any by Roman land surveyors. Decaying fortifications were refurbished, new tenements were designed and, as in York, craftsmen were starting in business almost overnight, producing a great variety of commodities for the surrounding rural markets. Alfred's kingdom was on its way from being an underdeveloped economy to one which, seventy years later, was one

of the richest in western Europe.

The industrial revolution was necessarily supported by changes of comparable scale in the countryside. Rescue excavations at Raunds in Northamptonshire¹¹ have charted the emergence of the medieval village, and it is a pattern now noted in many other places. The middle Saxon farm was evidently transformed between about AD 850 and 950, when it became part of a collection of farms focused for the first time on a manor and a parish church. Indeed, the manor and parish church seem to be features of the revolution as local lords and the Church tried directly to control agrarian resources. In the tenth century the number of rural communities expanded rapidly.

The scale of this revolution is mainly a measure of late Saxon and Anglo-Scandinavian government. Powerful centralized kingship was a feature of England from the Viking age to the Norman conquest and in complete contrast to the diffused authority of most continental kings¹². The authority and the capacity to introduce markets and the market principle to Anglo-Saxon England is a measure of political control¹³; to execute it on the scale witnessed in these excavations is a measure of the nation's wealth at that time.

A generation of rescue archaeology, therefore, has shed light on a momentous movement. With the agrarian and industrial revolutions of Alfred's age the form of present-day landscapes and townscapes in

Britain took shape. But archaeology on this scale offers more than a chance to reassess local history; it makes it feasible to calibrate the management of resources and to examine the social implications of such strategies. It is certain that the identification of this first English industrial revolution is just one example of the opportunities to rewrite the history of the Roman and later medieval periods. Rescue archaeology has convincingly shown that mainstream history can be studied in the field as well as in the archive. □

Malaria vaccine

Components of a cocktail

from F.E.G. Cox

IN THE wake of spreading drug resistance, the search for a realistic malaria vaccine has taken on a new urgency — most workers now agree that this will have to consist of a 'cocktail' of antigens or, as the World Health Organization puts it, a multivalent vaccine. Rapid progress has been made in identifying and characterizing potentially protective antigens from malaria parasites at various stages of their life cycle. A major antigen of the male gamete of the rodent parasite, *Plasmodium yoelii*, which can elicit antibodies that block transmission of the gamete from mice back to the mosquito vector, is described on page 258 of this issue¹. The human equivalent of this antigen may eventually be an important constituent of a vaccine but needs to be considered in the context of all the other antigens contending for this final selection.

The complex life cycle of the malaria parasite (see figure) begins when sporozoites are injected directly into the bloodstream by a mosquito. The sporozoite is, therefore, an obvious target for immunization and the major sporozoite antigen of the human malaria parasite,

Plasmodium falciparum, has already been expressed in *Escherichia coli*² and has proven immunogenicity³. Equivalent antigens have been used to immunize laboratory animals with considerable success. Unfortunately sporozoites circulate for only a few minutes before entering liver cells where they undergo a massive phase of multiplication and acquire new antigenic specificity. The products of multiplication, merozoites, which are again antigenically distinct, invade red blood cells to initiate the most destructive multiplicative phase of the life cycle.

Relatively little is known about the stages preceding this initial red-cell invasion but the intraerythrocytic stages have been intensively studied. Many antigens have been detected and the potentially important ones appear on the surface of the dividing parasite (schizont) at a late stage and on the merozoites resulting from division. These antigens, which vary from species to species and even within species, have relative molecular masses (M_s) between 190,000 (19K) and 23K (ref.4). Purified and partially purified antigens have been used with some suc-

The life cycle of *Plasmodium* spp. in mammals. The main targets for the immunological control of malaria are: (1) anti-sporozoite (prevents entry into liver); (2) anti-merozoite (prevents entry into red blood cell); (3) anti-gamete (prevents fertilization). Wavy line indicates blocking. Redrawn from Cox, F.E.G. *Modern Parasitology* (Blackwell, Oxford, 1982).

cess to immunize laboratory animals; the protection seems to involve blocking attachment and invasion by the merozoites of fresh red cells. The merozoites themselves possess several distinct antigens associated with either the surface or internal organelles. The gene for at least one of these surface molecules has been cloned and expressed in *E. coli*⁵ and a surface antigen has been used to immunize monkeys with partial success⁶. Some of these antigens may be involved in attachment of the merozoites to the red cells.

The final stage of the life cycle begins when merozoites enter red blood cells and develop into sexual stages or gametocytes. These remain in the red cells while in the blood and possess yet different antigens. Normally there is no immune response against the gametocytes, but once they re-enter a mosquito, they leave their protective red cells as gametes and become vulnerable to any antibody that is also taken up with the blood meal. These are the stages studied by P. G. Harte, N. Rogers and G. A. T. Targett¹. Using a rodent model, *P. yoelii*, they have identified on the male gamete a major antigen with *M*_{42K} and several minor antigens of 67, 59, 57 and 35K. Mice were vaccinated with these purified antigens and later infected with *P. yoelii*. The infections progressed as normal and gametocytes formed. However, when mosquitoes were fed on the mice they failed to become infected. The mechanism seems to involve agglutination of the male gametes and the prevention of fertilization. The effects of immunization were dramatic; the parasite load in the mosquitoes was reduced by 99 per cent following two immunizations.

There is every reason to expect that this kind of vaccination will be successful in primates, particularly as earlier work with crude antigens has already been confirmed in monkeys. These antigens, however, are not the only ones associated with the gametocytes and gametes; antibodies against the other antigens block

various stages of development and one even reduces the number of gametocytes in the blood⁴.

The real problem with human gametocyte or gamete vaccines is that they are specific to these stages and do not affect the course of the infection. This means that, for ethical reasons, they could not be used on their own — hence the need for a cocktail of antigens that would at least ameliorate the progress of the disease in man. Another problem is that there is still no rigorous mathematical analysis of the efficacy of such vaccines in the reduction of malaria transmission, so we really have little idea about how effective this method of preventing transmission might be.

There are problems other than the ethical ones. Although the emphasis has

been on antigens and antibodies it is clear that antibody-independent mechanisms are also involved in immunity to malaria⁷. At one time it was thought that a sporozoite, a merozoite and a gametocyte antigen mixture might do the trick but it now clear that the cocktail must be very complex indeed. □

Mathematics

The Bierberbach gambit

from Ian Stewart

THE theory of complex functions was the centrepiece of nineteenth century mathematics and is still of fundamental importance. It has been worked over thoroughly by generations of mathematicians, and one might imagine that everything worth knowing is now known; but in fact many outstanding problems remain. Among them was a conjecture in geometric function theory made by Ludwig Bierberbach in 1916, which bounds the coefficients in the Taylor series of a complex analytical function satisfying certain conditions.

Despite a sustained attack, the conjecture was verified only in a few special cases until last year when Louis de Branges obtained a complete proof, now available in preprint form (de Branges, L. *A Proof of the Bierberbach Conjecture* Mathematics Department, Purdue University). His method is a development of one used with partial success by Karl Löwner in 1923, and the final gap is filled by an inequality proved by Richard Askey and George Gasper in 1976, in the apparently unrelated (and unfashionable) field of special functions. Initially, de Branges's claim was greeted with scepticism. The tale casts an interesting sidelight on the sociology of mathematical research, as well as its content.

Geometric function theory, as its name suggests, deals with the geometry of transformations of the complex plane. It has its origins in the discovery that the transformations obtained from complex analytical functions are conformal, that is, do not change the angles between curves. Let the unit disk be the set of all complex numbers $z = x + iy$ with $x^2 + y^2 < 1$, and let $f(z)$ be an analytical function. Then f can be thought of as a way of deforming the disk, moving each z to its image $f(z)$. What shape can this image be? According to the

Riemann mapping theorem, anything! (More accurately, anything that is topologically a disk; that is, a simply connected open set.)

The image of the disk may overlap itself (and the Riemann mapping theorem must be stated with due care in that case), but there is an important class of functions f for which it does not. Such an f is said to be univalent on the unit disk. At this point the hint of a connection between topological and metric properties of f arises. The larger the image of the disk under f , the larger, in some sense, f is. The largest univalent function should transform the disk into the largest possible image, namely the entire complex plane. (Actually, for technical reasons, it is necessary to slit the plane along a line segment.) Does this statement make any kind of sense, and if so, what is this largest univalent function? (It looks as if it ought to be interesting in the sense that extreme cases always are.) An attractive guess is the Koebe function, $z/(1-z)^2$, which has the required properties. This has the power series expansion $z + 2z^2 + 3z^3 + \dots + nz^n + \dots$ and it occurred to Bierberbach that its extremality might be reflected in its power series. If so, the n th coefficient in the power series of a univalent function should be no larger than n . In other words, metric extremality should follow from geometrical extremality. It is an appealing, natural and simple idea; the sort of thing that ought to be possible to decide one way or the other without much trouble — but, in fact, a proof turned out to be decidedly elusive.

More precisely, consider a complex power series of the (normalized) form $f(z) = z + a_2z^2 + a_3z^3 + \dots$ which is univalent in the unit disk. The Bierberbach conjecture is that $|a_n| \leq n$ with equality holding only for a rotation of the Koebe function $f(z) = z/(1-\omega z)^2$ where ω is a constant of

absolute value 1. (The circular symmetry of the disk forces us to admit rotations as well as the Koebe function itself.) Until last year the conjecture was known to be true only for $n \leq 6$; this was proved by Bierberbach himself for a_2 , by Löwner for a_3 , by P. R. Garabedian and M. Schiffer in 1955 for a_4 , by R. N. Pederson and M. Ozawa in 1968 for a_5 and by Pederson and Schiffer in 1972 for a_6 .

De Branges's proof is obtained by way of two related conjectures. The first, due to M. S. Robertson in 1936, refers to 'odd' power series $b_1z + b_3z^3 + b_5z^5 + \dots$ univalent in the unit disk, and asserts the inequality $|b_1|^2 + \dots + |b_n|^2 \leq n|b_1|^2$. A simple argument shows that the Robertson conjecture implies the Bierberbach conjecture. In 1967 N. A. Lebedev and I. M. Milin proved an inequality about logarithmic coefficients of power series, which in 1971 led Milin to conjecture a further inequality which would imply the truth of the Robertson conjecture. It is this Milin conjecture that de Branges proves: the Robertson and Bierberbach conjectures follow immediately.

The method used by Löwner in his successful attack on a_4 is to introduce a partial differential equation whose solutions approximate any function univalent on the unit disk. This differential equation represents an expanding flow, and it is possible to push information along the flow — for example, estimates of the size of Taylor series coefficients. De Branges's proof introduces auxiliary functions τ_k to hold the desired information, each defined by a differential equation involving all previous $\tau_1, \dots, \tau_{k-1}$. If these functions can be shown to have certain useful properties, then the Milin inequality follows. However, the combinatorics of the sequence of τ s rapidly becomes very hard to manage. Walter Gautschi verified by computer that the desired properties hold for all values of n up to 25 (implying the truth of the Bierberbach conjecture for $n \leq 26$), and later noticed that the general result followed from a theorem of Askey and Gasper about Jacobi polynomials.

De Branges originally obtained his result as the climax of a 385-page typescript of the second edition of his book *Square Summable Power Series*, where it appears as a corollary to a general theory making heavy use of functional analysis. His announcement of a proof was greeted with some scepticism. De Branges had earlier claimed a proof of the Bierberbach conjecture that turned out to be fallacious, and this may have damaged his credibility.

The conjecture has a history of leading mathematicians astray. As Carl FitzGerald says in a survey (*Not. Am. Math. Soc.* 32, 2; 1985) of the conjecture and the circumstances surrounding its solution: "The Bierberbach conjecture is not difficult; I have proved it dozens of times". Acceptance came only after de Branges visited the Steklov Institute in 1984, when his proof was confirmed by the members

of the Leningrad Seminar in geometric function theory. E. G. Emel'ianov found a simplification avoiding the use of functional analysis which was examined by mathematicians in the West, who made some further simplifications and agreed that de Branges really had solved the problem. The proof has now been made very short and direct: one version takes only five pages (FitzGerald, C. and Pommerenko, Ch. *Trans. Am. Math. Soc.*, in the press). De Branges independently found a similar simplification.

So now we know that the Bierberbach conjecture has a short and simple proof, based on standard techniques in geometric function theory. Something very close to the successful assault must have been attempted by dozens, if not hundreds, of mathematicians. Why was the proof not found earlier? A likely reason is the subtlety of the problem. The precise approach that was successful is very delicate, and without a great deal of previous work, partial solutions and 'experimental' results, it is unlikely that anyone would stumble upon the particular combination of conditions needed to make the proof work. Another possibility is that most of the attempts were somewhat half-hearted, because nobody seriously thought that the standard approach would work. Mathematicians habitually talk of certain methods as being "worked out", in the mining sense that everything of value that can be extracted from them already has been. It is usually considered to be a waste of time to attack difficult problems by 'exhausted' methods. Yet, here it has suc-

ceeded. There are other mathematical cases. Dehn's lemma in topology and the complex version of the Hahn-Banach theorem baffled everybody for years but were eventually solved by methods that are so natural that the real puzzle is why the solutions had not been spotted immediately.

The answer may be related to the structure of mathematical proofs. As an analogy, consider a game of chess. Chess openings have been analysed by generations of Grand Masters in the hope of finding a novel line of attack and springing a trap on an opponent who finds himself in unfamiliar territory and under pressure of time. But there are so many possible variations in chess that a complete analysis of even up to a dozen or so moves is not feasible — there is still room for an original line of development only a little off the beaten track. Nimzovich caused his opponents many headaches by opening with a knight, a move so ridiculous that nobody had bothered to take it seriously. The 'opening moves' in a mathematical proof are far more varied than in chess. A line of argument may seem to be a poor opening simply because everybody who tried to play the game in that way followed a similar pattern of obvious but poor moves, missing a brilliant variation that would crack the game wide open. Certainly it is unwise to write off a plausible line of attack just because nobody has yet been able to make it work. □

Olfactory transduction

Welcome whiff of biochemistry

from Gordon M. Shepherd

As a detector of molecules, the olfactory receptor neurone is impressive, combining high sensitivity with a broad and rapid response. Given these properties, one might assume that the mechanism whereby these neurones transduce odour molecules into nerve signals would have been the subject of intense investigation. On the contrary, neuroscientists have gravitated towards the more tractable receptor mechanisms, such as those at the neuromuscular junction and in photoreceptors, where the stimulus is well defined and the receptors more accessible. Happily, the situation is beginning to change, and the report from Doron Lancet's laboratory on page 255 of this issue¹, of the apparent involvement of an odourant-sensitive adenylate cyclase in the sensory response, is an important step forward in the biochemistry of olfactory transduction.

The experiments were carried out in the olfactory epithelium of the frog (see Fig. 1). The initial step in odour transduction is believed to take place in the olfactory

cilia. Lancet's group obtained a cilia-enriched cell-free membrane preparation by dissecting out the simple nasal sacs of frogs, exposing them to a brief calcium shock, and differentially centrifuging out a preparation containing over 80 per cent cilia membranes. The basal level of adenylate cyclase activity in this preparation was almost 15 times higher than in either the whole epithelium or whole brain, where activity is also high. The adenylate cyclase activity was enhanced by GTP and compounds such as forskolin, and inhibited by guanosine 5'-O-(2-thio) diphosphate (GDP β S), thus meeting some of the common criteria for the activation of the adenylate cyclase by a guanine nucleotide binding protein (G-protein). And ribosylation catalyzed by cholera toxin permitted the identification of a polypeptide with relative molecular mass (M_r) of 42,000, suggesting a stimulatory G-protein (G_s) within the general class of GTP-binding proteins (also called N proteins) activated by hormones and neuro-

Fig. 1. Schematic diagram of the vertebrate olfactory epithelium. Mature receptor neurones arise during adult life by slow turnover of stem cells. Odour molecules are believed to act on receptor molecules (proteins?) in the membranes of the cilia and dendritic knob. Supporting cells have apical microvilli and are interconnected by a terminal web, as in other mucous membranes, thus limiting diffusion of absorbed molecules. They have glial-like properties and are believed to secrete the viscous mucus that bathes the surface. The thin watery mucus is thought to come from Bowman's glands.

transmitters.

If a G_s protein-adenylate cyclase system is involved in olfactory transduction, it should be affected by the presence of odour molecules. When the cilia preparation was exposed to a cocktail of four well-known odorant compounds, there was a GTP-dependent enhancement of the adenylate cyclase activity in a dose-dependent manner, at odour concentrations within the range of those used to stimulate receptor neurones in electrophysiological experiments.

From previous studies, it is known that field potential responses of the whole olfactory epithelium can be modulated by cyclic AMP analogues and phosphodiesterase inhibitors^{2,3}. The whole epithelium is a complex tissue (Fig. 1) in which the glia-like supporting cells and the glandular structures play undoubtedly important, but as yet undefined, roles. Because of these uncertainties and the limited data, the presence of a cyclic nucleotide cascade in the receptor neurones has been considered to be an open question⁴. The new study reduces the possibility of contamination by the other elements, and provides the clearest evidence yet of enzymatic processes related specifically to the sensory response.

The new data also fit nicely into an emerging outline for the sequence of steps that may be involved in olfactory transduction (Fig. 2a). Using this type of cilia-enriched preparation, Lancet's group has

previously reported the isolation of a 95K M_r glycoprotein that seems to be specific to the olfactory cilia⁵. They speculate that, like antibodies, this glycoprotein may have a constant and a variable region(s), the latter providing the diversity of sites required to account for the response of olfactory receptor neurones to a wide range of odour molecules⁶. Studies of other proteins that may be receptors are in progress elsewhere⁷.

By analogy with other second messenger systems, it seems a reasonable working hypothesis that binding of an olfactory molecule(s) induces an allosteric change in the receptor protein that causes activation of the G_s protein-adenylate cyclase cascade. One obvious advantage of this mechanism would be that the amplification built in to such an enzyme cascade would enhance the sensitivity of the receptor neurone; it could help to account for the ability of an individual neurone to be activated by single, or very few, molecules. Several types of receptor proteins might feed into the common enzyme pathway. Unfortunately, virtually nothing is known about the coupling of the adenylate cyclase to the presumed ionic channel(s) responsible for the receptor potential. This generates the impulse discharge that encodes the sensory response and transmits it to the brain.

The present report should provide a vigorous stimulus for further studies. Further biochemical characterization of the putative receptor protein and the G_s protein-adenylate cyclase pathway is urgently needed. Cloning of the genes for, and sequencing of, the olfactory receptor and G_s protein would then be not far from reach; the cloning of the gene for the α -subunit of transducin, the G protein in photoreceptors, has recently been reported⁸. Electrophysiological techniques have improved to the point where intracellular recordings can be routinely obtained from the olfactory receptor neurones, in spite of their very small size. Two possibilities deserve testing: first that the common action of cAMP causes phosphorylation of a channel protein and opening of ionic channels, resulting in the depolarizing receptor potential observed in response to odour stimulation; second, that there is a more direct effect on membrane conductance, similar to the direct action of cyclic GMP on membrane channels in rod photoreceptors^{9,10} (Fig. 2b). Whatever the mechanism, the extremely high sensitivity of olfactory neurones to injected currents suggests that small conductance increases, involving few channels, could produce large receptor potentials¹¹. Odour activation of single channels, and their control by adenylate cyclase, can be studied in patch-clamp recordings from cultured olfactory neurones¹² or in reconstituted membranes¹³.

Interest thus quickens. Perhaps there are other transducer mechanisms and pathways, such as through polyphos-

Fig. 2. a. Summary of proposed enzymatic cascade involved in olfactory reception⁶. b. The enzymatic cascade involved in visual reception^{9,14} for comparison.

phoinositol breakdown. The receptors could be modulated by neurotransmitters from autonomic fibres and nerve terminals, as well as by hormones carried through the rich vasculature of the epithelium. Perhaps the mechanisms of olfactory reception will turn out to be similar to those of the immune system, as noted above. There are intriguing similarities; for instance, as well as recognizing a variety of molecules, olfactory neurones are continuously generated throughout adult life from precursor cells (Fig. 1). If the analogy with the immune system finds support, we may eventually characterize olfactory transduction as involving 'odogens' which stimulate 'odobodies', leading to changes in activity of the intracellular enzymatic pathways discussed above and, perhaps, also to the release of extracellular signals that communicate with the surrounding supporting cells and regulate the differentiation of new receptor neurones from the precursor cells. Undoubtedly, there are pleasant surprises awaiting us right under our noses. □

Optics

Reflections on closed loops

from David K. Lynch

REFLECTION and refraction at the surface of gently rippled water produces images containing a variety of closed curves, the shapes of which depend on the spatial, or angular, distribution of the incident light field. The loops usually represent the distorted boundaries of high contrast features in the scene. In these columns¹ recently Thomas Gold discussed the formation of closed loops in reflections of linear objects such as the mast of a sailing boat, but point sources and objects extended in two dimensions also form closed-loop images. Here, I compare the loops resulting from reflection and diffraction of all three types of source.

All real sources are extended to some degree but sources that approximate to a point, such as the Sun and Moon, create a myriad of rapidly formed loops (Fig. 1), usually in the shape of distorted ovals^{2,3}. Because the water contains many surfaces inclined at precisely the correct angle to reflect light to the observer, the casual observer sees the loops — which form almost too rapidly to follow — coalesce to create the familiar glitter patch^{4,5}. These are readily seen in any body of water illu-

minated by a point source high overhead, such as bath tubs, swimming pools and coffee cups. The statistics of such reflections have been discussed by Longuet-Higgins², but the details of loop formation have not been well studied.

Theoretical studies of point sources show that there is not a one-to-one correspondence between the source and its image: that is, the solutions are not unique. For example, when the local radius of curvature of the water is twice the distance between the observer and the surface, the image of a point source is spread into a two-dimensional patch of light.

For linear sources of light such as masts, the reflected structure depends on the angle of the line of sight and the orientation of the source^{1,3}. Since a vertical mast separates two extended, nearly identical featureless regions, the blue sky seen inside a loop comes from one side of the mast and the blue region surrounding the loop comes from the other, a distinction that cannot be made for point sources.

With extended sources, such as mountains and clouds, the closed curves form landpools and skypools (W.C. Livingston,

First sight of Halley

CCD image of comet P/Halley (1982i) obtained on the 18 April 1985 with the 4.5-m Multiple Mirror Telescope of the Fred L. Whipple Observatory (MMTO). The integration time was 10 minutes and the seeing FWHM was 0.8 arc seconds. The comet image extends 5 arc seconds in the sunward direction with a brightness V of 18.7. The object at the top left is a binary star whose images have been smeared in following the comet's motion. The contoured bands of the cometary image indicate that the coma has been resolved. The image was digitally processed by K. Hege of MMTO. The first spectra from the coma are discussed on page 241.

Fig.2 (top) Skypools and landpools in a reflection of an extended source.
Fig.4 (bottom) Refracted images of the sandy bottom of a lake.

personal communication), regions of reflected blue sky light surrounded by darker regions from the landscape and vice-versa (Fig.2). Except for the distortion, landscape re-imaging is often extremely accurate on water in terms of surface detail. The reflected blue sky seems almost white at the boundary of the skypool. This is simply the reflection of the true brightness and colour distribution of the sky made readily visible because many tens of degrees of vertical sky are compressed into a small angle. However, skypools are not distorted images of the entire sky because only a small part of the sky is actually re-imaged; the upper and lower parts of the skypool originate from the same part of the horizon and approximate to mirror images.

Refraction can also render objects of all three categories into closed curves. The most common examples can be seen on the bottom of a swimming pool. High contrast point-like sources (most commonly the Sun) appear as loops, analogous to those formed by reflected points. Such linear sources, distorted by refraction, become the familiar bright webs on the bottom when light is focused by the wavy surface of the water⁶ (Fig.3). Because of dispersion, these loops also show brilliant colours. Extended sources, such as a bright rocky or sandy bottom, also display closed contours when viewed at low incidence. In these images the phenomenon is developed to its most fascinating complexity (Fig.4).

Much of the structure in both reflected and refracted distortions depends on the

Fig.1 Reflection of a point source: the moon.
Fig.3 Refracted image of a linear source from the bottom of a swimming pool.

duration of the observation and the spatial distribution of the source. If photographs of point sources reimaged by the water are taken with shutter speeds far shorter than the period of the waves, the image usually shows many sharp loops, together with partial loops caught as the shutter opens or closes in the middle of a trajectory. Exposures much longer than the wave period result in overlapping images. For a point source against a dark background, overlaps are simple but photographs of an extended source create patterns of colours and shapes that rival the finest impressionist art. □

Geomagnetic field

Volcanic record of reversal

from Jean-Pierre Valet, Carlo Laj and Piotr Tucholka

ON PAGE 230 of this issue Michel Prévot and his colleagues report the most detailed palaeomagnetic record of a reversal in the Earth's geomagnetic field to have been obtained from lava sequences¹. Because the type of rock in which the record is preserved determines certain characteristics of the record itself, it is of particular interest to compare some characteristics of the Steens Mountain record of Prévot *et al.* with similarly detailed records obtained from sediments.

Important data on the morphology of the transitional geomagnetic field have been obtained in the past decade from palaeomagnetic records of reversals. The first big step was the recognition that the transitional field is not dipolar². K.A. Hoffman then attempted to recognize an average field configuration³; in some cases there is an indication of axial symmetry⁴ but non-axisymmetrical components are present in most detailed results, both for single transitions⁵ and for sequences of reversals⁶. Although many attempts have been made to determine the harmonic content of the transitional field^{7,8}, further clarification of this problem needs records of transitions from the Southern Hemisphere.

The records have generally been obtained from sediments or from lava sequences. Magnetization of sediments is associated with the continuous process of sedimentation so that the resulting signal depends on the deposition rate and on the time necessary for the locking in of the remanence. If the acquisition process is very prolonged, the result can be a heavy smoothing of the signal. Laboratory studies^{9,10} have shown that magnetization is locked in at a depth of about 10–20 cm in the sediment, a value which has recently been confirmed by a novel method¹¹. Moreover, the pattern of the record itself can be used to determine the importance of this effect. Despite these apparent drawbacks, it is only sediments that can provide continuous, multiple records of the same transition from widely separated localities as well as records of sequences of reversals.

The magnetization in lavas is acquired in a very short time while the lavas are cooling down in the ambient field. Therefore, a sequence of lava flows provides a succession of instantaneous pictures of the transitional field and so is very sensitive to the rapid directional changes of the field on a very short timescale. Determinations of the absolute palaeofield intensity from lava, unlike sediments, are particularly reliable but, unfortunately, although the sequence of flows can be well established, it is impossible to determine the exact tim-

ing of the eruptions. Also, records from lavas provide neither verification of results from multiple profiles nor sequences of records from consecutive reversals.

The transition recorded at Steens Mountain in Oregon is characterized by the succession of two distinct phases, the first being a complete flip from normal to reverse of the vector, while the second is a normal–transitional–normal rebound. Most of Prévot *et al.*'s discussion is given over to the field variations associated with the second phase. During this period, the directional changes are mostly scattered far away from the meridional plane and the virtual geomagnetic poles describe large longitudinal variations. There are also two important directional jumps, which the authors interpret as geomagnetic impulses associated with global changes of the field with time constants of 1–2 years. Note that these impulses occur while the field configuration is away from axial symmetry. Following the suggestion of the authors that such impulses reflect an increase of the turbulence within the Earth's core, the results also suggest that the whole field configuration is affected by this increase. The authors note that time constants of the same order of magnitude as the impulses have been observed for the 1969 secular variation jerk. It is thus important to connect this observation with a recent theoretical prediction by J.L. Le Mouél¹² that some of the observed features of the secular variations should persist during a transition.

The two phases of the transition are separated by an episode of normal directions and pretransitional intensity values, which is interpreted by Prévot *et al.* as the temporary re-establishment of the dipole field configuration. In view of the thickness of the recording zone, they argue that the first episode lasted half the time of the second, so that the whole record would correspond to a single reversal. But this argument rests on the assumption that the volcanic activity was regular and uniform which is, at least, questionable.

Alternatively, therefore, it can be suggested that the polarity change was completed at the end of the first phase and that the second phase is a record of an excursion that is quite separate from the major reversal. Of course, this interpretation implies very different characteristics of the transitional field, closer to those that are commonly observed in sediments. In particular, the directional changes are much more regular and the resulting directional path is highly confined in a narrow longitudinal band, suggesting a degree of organization of the transitional field. We note also that the first fast

impulse lies well within the meridional plane. Fast changes within transition paths are also apparent in sedimentary records but are often disregarded as possible disturbances of sedimentary or other origin. Perhaps in the light of the Steens Mountain results they will merit new consideration.

If the second episode reflects an excursion of the geomagnetic field that is unrelated to the polarity reversal, the Steens Mountain record provides evidence that the field behaviour associated with these two phenomena is different. The core processes during reversals and excursions would, at least in this case, not be intimately related. In particular, the hypothesis of K.A. Hoffman¹⁴ that palaeomagnetic excursions are aborted reversals would not be valid.

Although Prévot *et al.* certainly have written an important chapter, the history of palaeomagnetic records of transitions is not finished. Our knowledge of the transition field should be increased by multiple and detailed records of the same reversals. Thus, records from sedimentary sequences offer the most promising per-

spectives. In particular, very important results can be expected from records with very high sedimentation rates. This should allow time resolution in a range similar to that which is possible for volcanic rocks and so should lead to a reconciliation of the sedimentary and volcanic records. □

Climate modelling

The climate as natural oscillator

from Gerald R. North

THE Earth's climate exhibits great variability at timescales centred at 100, 41 and 20 kyr, as shown convincingly by J. Hays *et al.* (*Science* **134**, 1121; 1976) using data from marine sediments. As these oscillations happen to be the dominant periods of the variations in the Earth's orbital elements (eccentricity, obliquity and perihelion at summer solstice), they have stimulated a revival of the astronomical theory of the Quaternary glaciations (see *Milankovitch and Climate* eds Berger, A. *et al.* Reidel, Dordrecht, 1984).

Steady-state atmospheric climate models show remarkably little sensitivity to orbital changes, leading to a major crisis in climate theory over the past decade. An interesting line of reasoning has been pursued by Barry Saltzman and colleagues (for example, *J. atmos. Sci.* **41**, 3380; 1984). To avoid the issue of sensitivity, Saltzman suggests that the system is a natural nonlinear oscillator with a period of about 100 kyr. The tiny orbital forcing merely acts as a pacemaker providing a phase and precise frequency to lock with.

Although it is premature to call the Saltzman theory conclusive, its elegance and generality make it essential reading for ice-age buffs. The model is highly idealized, keeping track of only a few important dependent variables. It consists of a set of first order (in time) differential equations — the prognostic equations — for the perturbed variables: land-ice volume, sea-ice volume and deep ocean

temperature. The differential equations are coupled through simple polynomial forms up to the third degree in powers of the variables. The solution for equilibrium (all variables vanishing) exists, but it is unstable to infinitesimal perturbations from equilibrium for reasonable values of the coefficients in the system. The free solution state is quickly drawn away from the origin to a limit cycle with a period of about 100 kyr.

The dominant physical process in the model is the sea ice cover. When it is large, the planet has a large albedo leading to an overall cooling and further growth of ice volume by expansion of the freezing line towards the equator. On the other hand, large areas of ice-covered ocean inhibit evaporation and therefore starve the glaciers. Other feedbacks, such as inhibition of heat transport towards the pole under the sea ice and the subsequent buildup of deep ocean temperature, act in the same general manner. If the time constants for these processes are different enough they can lead to oscillations with rather asymmetrical growth and decay time characteristics. The longest time constant introduced in the problem as a parameter is about 7 kyr in the thermal inertia of the deep ocean. The nonlinear dynamics of the system translates this relatively short timescale into the much longer natural oscillation period. The sharp termination of ice volume in the data is one of the unanswered questions about the 100-kyr

cycles. This sawtooth time series, consisting of slow ice growth and abrupt terminations, seems to be a natural property of the Saltzman model, arising from the differences in time characteristics of the individual components. Parameter sensitivity studies show that the essential character of the oscillation is unchanged by small departures from the nominal values.

Although the Saltzman model is attractive because of its logical consistency and systematic formulation, it is not alone in the arena of contenders for ice-age glory. M. Ghil and colleagues (*J. geophys. Res.* **88**, 5167; 1983) suggest an oscillator model based on a short natural period (about 10 kyr). When driven by the Milankovitch frequencies, the solutions exhibit combination tones, one of which is near the 100-kyr period. In their theory, R. Peltier and J. Hyde (*J. atmos. Sci.*, in the press) emphasize feedbacks associated with the bedrock response. The latter theory does not exhibit free undamped oscillations, but it does seem to have a strong response at the 100-kyr period when driven by a forcing frequency near a harmonic of this natural period, say 20 kyr.

There has never been a shortage of ice-age theories, because many of the component processes of the system cannot yet be modelled. The result is a group of schemes replete with free parameters and fudge factors — the Saltzman theory has about 10 such factors and others are comparably endowed. The biggest challenge facing the ice-age system theorist seems to be finding a risk that a model can run in the face of hard evidence as opposed to fitting the lone time series of ice volume. In terms of fitting the ice volume time series it is hard to surpass the phenomenological model of J. Imbrie and J. Z. Imbrie (*Science* **207**, 943; 1980), purely because of its simplicity. The model included one time constant for ice volume growth, one for its decay and a scale parameter for the forcing strength. The result was a rather good fit to the sawtooth time series. The main task now faced by modellers is to construct theories that derive these parameter values from more fundamental principles.

The Achilles heel of simplified theories modelling time behaviour of ice volume is their sensitivity to the parameterization of snowfall over the ice sheets. This is especially grim as the most detailed general circulation models of the atmosphere seem unable to compute the precipitation rates adequately, particularly near the poles — just where it counts in an ice-age theory. The next decade may lead to a better understanding of such precipitation, producing a breakthrough comparable to geological evidence in terms of eliminating classes of ice-age theories. Meanwhile, modellers can explore the vastness of parameter space unconstrained by cruel realities. □

Simpler DNA sequence representations

SIR—The method of DNA visualization presented by Hamori^{1,2} admits of a simpler representation which may be more generally useful. In Hamori's technique, each of the four nucleotides is represented by a vector in three-dimensional space having a characteristic, but variable, orientation. DNA structure then may be viewed from any chosen perspective in two-dimensional plots on computer graphical monitors. Different aspects of structure are examined by varying the geometric relationships among the four elemental vectors.

I suggest that a particular, canonical choice of vectors has certain advantages, both for exploring structure and for comparing sequences. Figure 1 illustrates an intronic sequence based on this approach, wherein successive guanine (G) residues are represented by unit vectors in the positive x-axis direction, complementary cytosine (C) residues correspond to negative x-axis unit vectors, and thymine (T) and adenine (A) residues correspond to unit vectors in the positive and negative y-axis directions respectively.

With this choice, all sequences can be represented in two dimensions in a unique manner, and differences in sequence structure become immediately apparent. In Fig. 2, which compares two actin genes, the regions of divergence of the exonic sequences are clear.

Furthermore, this method of embedding DNA sequences in a two-dimensional metric space permits the consistent application of several standard concepts based on distance measures. Two are worth mentioning. Plots of cumulative Manhattan distances from a site of origin (for example, the initiation codon) against position number can be useful in pinpoint-

Fig. 1 Graphical representation of the 186-base pair (bp) nucleotide sequence of human BK papovavirus BK enhancer³, showing three 12-bp repeats. The sequence begins at the bottom, at coordinate position [0,0], and reads (5' to 3') towards the top. Successive G, C, T and A nucleotides are depicted as coordinate shifts of one unit in the +x, -x, +y and -y directions, respectively.

Fig. 2 Nucleotide sequence representations of two actin genes from *Drosophila melanogaster* (Canton S strain). The single intron has been removed from each, leaving a 1,131-bp exonic sequence. Data were obtained from the GenBank library. a, Cytological locus 79B; b, cytological locus 88F.

ing similarities in structure of sequences coding for the same type of product; this ideally should be done after alignment for maximum sequence homology.

Finally, the general properties of classes of sequences (for example, actin genes from different groups of organisms, different types of immunoreceptors) can be examined by calculating the fractal dimension, in this space, of each sequence. This is simply the ratio of the logarithm of the total Manhattan path length to the logarithm of the distance of the end-

point of the sequence from its origin: $\log [n(A) + n(G) + n(T) + n(C)] / \log [n(G) / n(C) + |n(T) - n(A)|]$, where $n(X)$ is the number of occurrences of nucleotide X in the sequence.

Similarity of vaccinia 28K, v-erb-B and EGF receptors

SIR—Vaccinia virus, a member of the Poxviridae, has a large, double-stranded DNA (about 187,000 base pairs) and replicates in the host-cell cytoplasm. The genome contains more than 100 genes, some of which probably code for the enzymes involved in the viral transcription process. Recently, similarities were found between the sequences of the vaccinia 19K protein, EGF, transforming growth factor type 1, and several other mammalian proteins¹⁻³.

Using the FASTP rapid similarity search⁴ and other programs of the Protein Identification Resource system, we have now found unusual sequence similarity (Figs 1,2) between the vaccinia virus 28K proteins a major late protein of unknown function, synthesized after DNA replication and the carboxyl ends of the v-erb-B transforming protein of avian erythroblastosis virus⁵ and, to a lesser extent, the related human epidermal growth factor (EGF) receptor precursor⁷.

When we used the ALIGN program to evaluate these similarities, the 28K protein and a portion (345-584) of the carboxy-terminal domain of the v-erb-B protein produced an alignment score of 4.9 s.d. (mutation data scoring matrix with 6 added to each term, penalty of 6 for a break in either sequence, 300 random

Fig. 1 Graphic matrix plots of the vaccinia 28K protein, the v-erb-B protein (350-604), and the EGF receptor precursor (920-1,170). Each point represents a score of 20 or more over a span of 25 amino acids using the mutation data scoring matrix.

Fig. 2. Alignment of vaccinia 28K protein (28-229), v-erb-B protein (372-562), and EGF receptor precursor (952-1,140). Identities between the 28K protein and either of the other two are boxed.

permutations). A score of 7.2 s.d. was obtained if portions of the 28K protein (28-229) and the v-erb-B (372-562) were compared. Comparison with a portion (952-1,140) of the cytoplasmic domain of the precursor EGF receptor produced a score of 5.6 s.d. Because of the exhaustive nature of the FASTP search, values in this range indicate a very interesting similarity that is likely but not certain to have biological significance⁴.

Such similarity can result from common ancestry or from convergent evolution of proteins with similar structures or functions. For example, it may be advantageous for the virus to mimic certain host proteins. It remains to be seen if more vaccinia proteins have sequences similar to host proteins. Perhaps the relationship between vaccinia virus and its host cell will become clearer when the entire genome of this virus is completely sequenced and more host sequences are available.

Did Burton synthesize diamonds in 1905?

SIR—In a letter to *Nature* of 24 August 1905¹, C. V. Burton, a prominent physicist, claimed to have synthesized diamond at ambient pressure by an unusual method. It may seem odd that the first response to this communication should appear some 80 years later, but the strange fact is that, for some inexplicable reason, this disclosure was lost to the literature.

Although a brief abstract appeared in *Science Abstracts*, it was not abstracted by any of the three chemical abstracting journals available at that time nor has any chemical treatise concerning carbon referred to it. Despite the voluminous literature relating to synthetic diamonds, not one author has referred to Burton's work. By chance, one of us (F. S.), found a reference to Burton's letter in a book on gem

stones by W. Goodchild², published in 1908 when the memory of Burton's disclosure was still fresh in the author's mind. Burton gave only a skeleton outline of his procedure and promised a further communication. However, a meticulous search has not disclosed such a communication.

Although Burton claimed to make diamond in the region of temperature and pressure in which graphite was the stable form of carbon, there is no reason why he should not have been successful in obtaining diamond in a metastable state. His method was to dissolve carbon in a lead-calcium alloy in which carbon is more soluble than in lead alone, then supersaturate the lead by oxidizing the calcium with steam at a "dull red heat" thus removing it from the alloy. The carbon precipitated in the form of diamond. Ostwald's law of successive reactions, also now lost from physical chemistry textbooks, provides for a metastable phase to appear before the stable phase, and at 500°C, the conversion of diamond to graphite is exceedingly slow. The data Burton gave on the crystals he obtained, their octahedral form, the refractive index, and the resistance to chemical attack are consistent with his claim to have made microscopic diamonds.

We have attempted to repeat Burton's work. In the absence of any experimental details, it is difficult to be sure that we followed his procedure exactly, and we had some difficulty incorporating the carbon in the alloy but we successfully solved that. We decomposed the alloy with steam at 550°C, our estimate of a dull red heat. The grey crust was treated with acid and washed well to remove all lead and calcium salts. We obtained a black powder in which were embedded many transparent crystals which scintillated with considerable fire in reflected light. They were at most a few micrometres in size. Burton claimed that he made only diamonds and no graphite. We obtained considerable amounts of black powder which may or may not have been graphite which made it impossible to separate the tiny crystals for precise identification. The crystals had a high refractive index and the powder scratched glass. X-ray powder diffraction showed a strong peak at 0.208 nm which is the strongest peak for diamond, but only weak for graphite. Strangely, the

strongest peak for graphite was absent, though two other peaks at 0.161 nm and 0.148 nm were still present. The strongest peak was an unidentified one at 0.251 nm. On the basis of this information, we cannot claim unequivocally that diamond was produced, but combined with the other properties, there is a strong presumption that diamonds were made and, therefore, Burton had synthesized diamonds in 1905, half a century before General Electric had made them in the stable region of high temperature and pressure. He deserves recognition in the Hall of Fame which includes Moissan and Hannay.

Thanks are expressed to the National Science Foundation for providing a grant to enable this work to be done, to L. W. Zelazny for his help in providing the X-ray data, and to F. D. Bloss for assistance with the refractive index.

Misapprehension over Alzheimer's disease

SIR—Stanfield *et al.* make the *en passant* observation that degeneration of the neurones of the nucleus basalis of Meynert "are the likely cause of Alzheimer's disease"¹. This is not so. However, it is a widely held misapprehension. Other nuclei besides the nucleus basalis are similarly afflicted with tangles and show similar cell loss in Alzheimer's disease^{2,4}: lesions to the nucleus basalis area in animals produce few of the clinical and none of the pathological symptoms of Alzheimer's disease. The article commonly quoted⁵ as support for the cholinergic hypothesis has the beautifully ambiguous title "Alzheimer's disease: a disorder of cortical cholinergic innervation". This title is correct in only one of its senses.

Essential for all Chemists

When you work or study in a field which is changing as fast as spectroscopy and chromatography it's not easy to keep up-to-date with all the new developments. New instruments are constantly appearing on the market and new techniques are being evolved in one of the fastest growth areas of modern science.

These dictionaries of chromatography and spectroscopy, already highly acclaimed in their previous edition, will enable you to:

- * broaden your knowledge of new products and instruments
- * obtain rapid explanations of new terms and techniques
- * relate your own speciality to other areas
- * check symbols and equations quickly and efficiently

A Dictionary of Spectroscopy covers such areas as atomic spectroscopy, emission spectroscopy, electron spin resonance, infrared and ultraviolet spectroscopy, nuclear magnetic resonance, photoelectron spectroscopy, photoluminescence, mass spectroscopy and Raman spectroscopy.

A Dictionary of Chromatography covers gas chromatography, gas liquid and gas solid chromatography, liquid chromatography, paper chromatography and thin layer chromatography.

Both dictionaries are clearly illustrated with over 50 drawings and diagrams and give numerous references for further specialised reading.

An uneasy relationship

D. M. MacKay

Cross-Currents: Interactions Between Science and Faith.

By Colin A. Russell.

Inter-Varsity Press, Norton Street, Nottingham NG7 3HR, UK: 1985. Pp.272. £7.95.
To be published in the United States in August by W. Eerdman.

THE popular image of science has undergone some curious reversals of fortune over the past century. Fifty years ago, the rabble-rousers of the *avant garde* preached the gospel of "scientific humanism", according to which science was the ultimate answer to all the problems besetting mankind, including those traditionally the province of religion. In more recent years the fashionable trend has been to turn upon science as itself the origin, rather than the remedy, of the ills of our age.

In times like these the corrective of a broader historical view is much needed, and Colin Russell's book seems admirably designed to meet the need. As Professor of the History of Science and Technology at the Open University he has both the knowledge and the communicative skills to bring alive the ways in which religious and scientific ideas have interacted over the centuries to shape our conception of the natural world. Following in the footsteps of such pioneers as R. Hooykaas (whose classic *Religion and the Rise of Modern Science* is frequently cited), he shows how from early Greek times onward people's ideas of God, or the gods, have coloured their attitude to nature and helped or hindered their efforts to understand it. In the end, refuting popular ideas to the contrary, he is able to marshal "powerful historical evidence of a massive mutual debt between Christianity and science":

Conflict there has certainly been, but always for reasons that are peripheral to the real issues with which science and Christianity are concerned. Only in that limited, even localized, sense has there been anything like even an "uneasy truce". Desperate attempts to evacuate the Christian faith of its essential content, so as not to offend the susceptibilities of "scientific man", are not merely misguided but leave most scientists profoundly unimpressed [p. 252].

More negative historical phases are not neglected. The mixed reception given to Copernicanism is carefully analysed, and the popular notion that the heliocentric model was seen by contemporaries as a "demotion of man" is cogently questioned. Rhetoric's long-lost treatise designed to demonstrate Copernicus's orthodoxy, recently re-discovered by Hooykaas, takes a line rather similar to Kepler's in pleading that Holy Scripture (with its poetic references to the "fixity" of the Earth) was not intended to be used as a textbook of science. One gets the impres-

sion that if Galileo had been a little less aggressively tactless, the Roman Church might have been coaxed to recognize in time (rather than two centuries after the fiasco of his trial) the theological innocence of his proposals.

The part played by Puritanism in the rise of modern science has been much debated since R. K. Merton highlighted it. Russell gives a fair picture of the controversy, concluding that

underlying the bewildering variety of parties associated with science was a common core of biblical allegiance common to Puritanism, to the wider Calvinism and indeed to Protestantism as a whole. Of the resonance between that allegiance and the growth of science there can be no possible doubt [pp. 83-84].

Moreover

[People] are surprised that the tight-lipped, joyless exponents of an iron religious creed could ever unbend to consider such frivolities as scientific experiments, let alone have the wit to understand them. Yet that is only because "Puritan" and "puritanical" are given a totally unhistoric meaning today. The early Puritans, like Bunyan, did take their faith seriously, but they laughed and made music and love like anyone else, and they, more than their contemporaries, delighted in the world of nature [p.82].

An illuminating section on the Darwinian controversy draws on recent scholarship, especially on the work of J. R. Moore, to reassess the parts played by religious (and anti-religious) convictions among both supporters and antagonists of evolutionary theory. Despite their hostility to the established Church, T. H. Huxley and his Victorian friends were curiously soft-centred in their attitude to nature — almost as if they hoped to find in "her" the God they had lost. Huxley's view that "living nature is not a mechanism but a poem" typifies the Romantic strain in much agnostic thought of the day. Russell gives some fascinating glimpses of the pseudo-religious fervour with which the new and optimistic "scientific" creed was followed. It would seem (though he does not directly say so) that the aggressively anti-religious X-club founded in 1864, together with such vocal protagonists of "Victorian scientific naturalism" as J. W. Draper and A. D. White, showed in their vehemence and their disregard for awkwardly relevant facts quite as much extremism as we nowadays deplore in anti-evolutionary fundamentalism. Conversely, Russell makes clear that a num-

ber of convinced Christians were from the outset enthusiastic (perhaps too uncritically so) in support of Darwin's biological theory (as distinct from the atheistic metaphysics that borrowed its name and prestige). The fact that men of the stature of Joule, Maxwell, Kelvin and Faraday remained quietly convinced believers is also cited against any idea that the leaders of Victorian scientific thought, as a body, felt themselves to be at war with religion.

The concept of science as a potential boon to man, of which Francis Bacon made so much, was evidently alive already in the thirteenth century. It is all the more curious that, despite the declared endorsement of it by the fledgling Royal Society, this idea for so long bore so little

Victorian protagonists — T. H. Huxley (left) and Michael Faraday.

practical fruit in technology. Painstaking improvements in craftsmanship brought rich dividends. Advances in the design of chronometers, for example, revolutionized the art of navigation. But according to Russell it is not until the middle of the nineteenth century that we find scientific insight as such contributing significantly to technological advance; and even then, as the story of thermodynamics shows, the traffic was by no means all one-way.

Readers who wonder how some modern bishops' views on miracles fit into the historical picture will find Colin Russell well prepared to answer; and chapters on the impact of quantum theory on theology, and of the Christian doctrine of stewardship on ecological thinking, ensure that contemporary issues are not overlooked. Though Professor Russell writes as a Christian, he maintains a judicial posture and a scholarly regard for documentation that makes his book specially suitable for students and those concerned to see the record straight. Appetizing as well as authoritative, it should be required reading for teachers of science as well as of religion, whether in or out of the pulpit. □

Cloning cookbook for the laboratory

Kevin Struhl

A Practical Guide to Molecular Cloning. By Bernard Perbal. Wiley: 1984. Pp.554. Hbk £68.85, \$59.50; pbk £39.90, \$34.50.

TEN years ago, molecular cloning was an art that was practised only in a few Californian laboratories. Now, with everyone and his brother involved in recombinant DNA manipulations, the field has exploded into a vast and complex technology that is far beyond the ability of an individual to learn and remember completely. Furthermore, because these techniques have become invaluable in almost all fields of biological science, it is frequently the case that those who want to use them are not trained as molecular biologists. In short, there is a great need for a cookbook, which contains a reasonably complete collection of recipes that are easy to follow and up to date.

Three years ago Cold Spring Harbor Laboratory published such a collection, *Molecular Cloning: A Laboratory Manual* by Maniatis, Fritsch and Sambrook. This book is omnipresent in molecular biology laboratories and is utilized to the point where it is frequently referred to as "The Bible". Although experts usually use shortened versions of the procedures, the methods are clearly described and they do work. Indeed, the only shortcoming of this manual is its age. It does not contain anything on the production of monoclonal antibodies and related methodologies, now standard tools of the trade, and the section on expression vectors for the controlled production of gene products is weak and out-dated. An updated version is clearly necessary, and the authors are, in fact, preparing a new edition.

What does *A Practical Guide to Molecular Cloning* offer that the earlier book lacks? Unfortunately, the answer is not much. The most practical addition is that of DNA sequencing using single-stranded DNA vectors and primer extension with di-deoxy nucleotide precursors. However, most commercial suppliers enclose an equally detailed protocol on purchase of the reagents. The author also describes a number of techniques for the purification

of large quantities of DNA. These methods are seldom used and the descriptions read suspiciously like the promotional literature from the companies that sell the products.

Given the need to include newer techniques, Perbal devotes an inordinate number of pages to unnecessary matters. More than 20 per cent of the book is spent on lists of restriction endonucleases and vectors; such information, although useful, is easily found in the catalogues of commercial enzyme suppliers. Thirty-three pages are devoted to a "theoretical study of the fraction of a long-chain DNA that can be incorporated in a recombinant DNA partial-digest library" and the representation of DNA sequences in such libraries. I don't know anyone who uses this information on a practical basis; moreover, the few qualitative aspects worth knowing are buried among pages of mathematical formulae.

Members of my laboratory found Per-

bal's book much harder to use than its competitor. One problem is that the book is bound in a conventional fashion, as compared to the earlier manual which comes as a spiral notebook. This seemingly trivial difference is actually of practical importance because Maniatis *et al.* lies flat and is thus easy to read on a laboratory bench, its natural habitat. Another problem is that the experimental protocols appear in large print, whereas explanatory paragraphs appear in small print. This is visually uncomfortable, and the large print for the protocols coupled with the small page size means that many techniques are spread out over a number of pages.

Thus it seems to me that the Maniatis *et al.* manual is still the best around, and the revised version should be even better. □

Genesis of man

Harry V. Merrick

African Archaeology. By David W. Phillipson. Cambridge University Press: 1985. Pp.234. Hbk £25, \$39.50; pbk £9.50, \$14.95.

OVER the past two decades the pace of prehistoric archaeological research in Africa has accelerated enormously. Although recent work frequently has not produced as visually spectacular discoveries as in other parts of the world, it has been of the first order of importance in elucidating earlier human behaviour, especially during the Stone Age. Far from being a culturally stagnant cul-de-sac during the course of human evolution, Africa has often displayed a technological precociousness that would have astounded prehistorians 20 years ago.

In this book Dr Phillipson has brought together the new findings with earlier research to produce a very readable, relatively non-technical survey of the current state of knowledge of African prehistory. It is both timely and urgently needed; the last comparable synthesis is now 15 years old and has been largely superseded by recent events.

African Archaeology is very much a traditional, narrative account of the main stages of human development in Africa, emphasizing subsistence patterns and general ways of life. Each stage is presented in a series of regional summaries, accompanied by illustrations of the principal sites and representative tool and pottery types. Fortunately, much of the nomenclature and the intricacies of stone tool classification, which have dominated chronological and cultural reconstructions in African prehistory, are

neatly bypassed using Grahame Clark's scheme of technological modes to describe levels of technological complexity without temporal connotations. Nonetheless, details of chronology and technology still loom large for the first two million years of prehistory recounted in the first third of the volume. However, for the past several millennia, and especially for the Sub-Saharan region, Phillipson combines the findings of archaeology, including results from his own considerable field work, with linguistic and historical evidence and oral tradition to produce a much fuller view of emerging African societies in each part of the continent. This is an approach which also encourages appreciation of some of the environmental, economic and social factors underlying the cultural diversity of modern African peoples.

The bold attempt to encompass over two million years of a continent's prehistory in a single volume has understandably necessitated a synoptic treatment of most of the more controversial issues in African prehistory. While the superficial treatment of these problems may be trivial in the broader context of a continent-wide survey, regrettably it represents a missed opportunity to convey the excitement in African archaeological research today and the increasing inclination towards problem-orientated research. That apart, the book is impressively comprehensive, well-referenced and concise. It will be of particular interest to a broad range of Africanists and archaeologists, and of value as an introductory textbook for courses which cover African prehistory and history. □

New in paperback

- *Quarks, Gluons and Lattices* by M. Creutz. Publisher is Cambridge University Press, price is £7.95, \$12.95. For review see *Nature* 309, 290 (1984).
- *From Folk Psychology to Cognitive Science: The Case Against Belief* by Stephen Stich. Publisher is MIT Press, price is \$8.95, £8.95. For review see *Nature* 309, 815 (1984).
- *Ontology and Phylogeny* by Stephen Jay Gould. Publisher is the Belknap Press of Harvard University Press and the price is \$8.95, £8.25.

Of the highest order

W.C. McGrew & J.R. Anderson

The Natural History of the Primates. By J.R. and P.H. Napier. *British Museum (Natural History)*: 1985. Pp.200. £15. To be published in the United States later this year by MIT press.

Primates in Nature. By Alison F. Richard. W.H. Freeman: 1985. Pp.558. Hbk \$27.95, £32.95; pbk \$17.95, £13.50.

IN 1967, the Napiers' *A Handbook of Living Primates* appeared and immediately became the standard reference source for primatologists. Now the same authors have written another, slimmer reference work. There are several similarities between the two books: in each the bulk of the text is made up of potted profiles of primates arranged by genus, although the proportion given over to these has dropped in the new book, and some of the photographs and figures are the same as before. The differences, however, suggest that *The Natural History of the Primates* is aimed at a wider, more popular audience. New features are the inclusion of colour plates, a more spacious, double-columned lay-out and use of British as well as metric measures, while there is minimal citation of sources and only a short reference list. The writing is lively and clear, and the last chapter on human evolution packs a lot into only ten pages.

But the book does not fare so well in its stated role as a textbook. The content is sometimes repetitive (for example, three times, on pp. 19, 31 and 53, we are told that marmosets have claws and not nails) and is also somewhat old-fashioned in places. Key advances in the sociobiology and behavioural ecology of primates made over the past 15 years are rarely mentioned. Thus, for example, predators on primates are described as "beneficial" in helping to maintain the prey species as a "balanced viable population". Overall, this is a book which will better serve the keen amateur than the student or professional.

By contrast *Primates in Nature* is remarkable for its breadth of approach and the depth of ecological information provided; it deserves to become a cornerstone in the primatologist's library. One of the author's aims was to treat primates "as mammals rather than as our closest living relatives", that is to illuminate ecological generalities as well as features particular to primates, as in the adaptations of certain langurs and macaques to the problems of living in seasonally harsh temperate zones. Such comparisons do not dominate the book, however. Apart from a discussion of social organization in African hunting dogs and lions, non-primates take a back seat in Chapters 4-10 which concentrate on what is and is not

known about primates: as individuals (feeding, diet, reproduction), populations (demography), groups (social organization) and communities (interspecific relationships). The final chapter compares the position of primates and non-primates in ecological communities.

Dietary constituents and their distribution in plants are described lucidly in Chapter 4, followed by accounts of the feeding regimes of various species and of some of the corresponding morphological adaptations, notably dental and gastrointestinal. Some may feel that vertebrate prey are dismissed rather casually, for example in view of known seasonal and individual variations in meat-eating in chimpanzees. The same could be said for insectivory: while specialist insectivores

Demidov's Bush-baby taken from *Monkeys and Apes* by Gotthard Berger and recently published by Arco. The price is \$24.95.

get their fair share of attention, insect-eating by non-specialists is passed over more quickly.

The author has adopted a case-history approach in describing aspects of primate ecology, illustrating a number of topics such as reproductive parameters, demographic patterns, social organization and so on with examples drawn from a range of species. This provides a broad perspective on primates as an order, and it is good to see prosimians and callitrichids given equal place alongside their larger and better-known counterparts. Anyone studying a field-site with more than one species of primate will benefit from reading Chapter 10 on sympatry, competition and the niche.

Primates in Nature does not include many data on social behaviour, for instance on grooming rates and on mother-offspring interaction. But it does contain solid background reading, a glossary of ecological terms and a wealth of ideas for preparing a primate field study, all in highly readable style. □

W.C. McGrew is Senior Lecturer in Psychology at the University of Stirling, Stirling FK9 4LA, UK, and J.R. Anderson is Maître-Assistant in the Laboratoire de Psychophysiologie, Université Louis Pasteur, 7 rue de l'Université, 67000 Strasbourg, France.

Got that loving feeling

Michael Shepherd

Aphrodisiacs: The Science and the Myth. By Peter V. Taberner. Croom Helm/University of Pennsylvania Press: 1985. Pp.275. £19.95, \$22.50.

WHAT IS an aphrodisiac? According to Peter Taberner, it is, strictly speaking, an exciter of lust; more generally, "anything which, by any means, increases the capacity for sexual enjoyment". With this definition he has given himself a broad canvas on which to sketch a readable, fact-filled review that roams over the wilder shores of sexuality.

As a professional pharmacologist the author is well qualified to discuss the properties and adverse effects of both the relatively small number of sexual stimulants in the medical pharmacopoeia and of the drugs of abuse which are used for their supposedly aphrodisiac properties. These constitute, however, no more than a small proportion of some 500 animal, vegetable and mineral substances listed in one of the appendices which have been or are being used as putative aphrodisiacs and to which reference is made in the text.

As its title indicates, the book is concerned with myth as well as science, with witchcraft and wormwood as well as bromocriptine and brain stimulation, with anthropology and medical history as well as the endocrinology and neurophysiology of sexual behaviour. The attainment of heightened sexual satisfaction ranks with gold, immortality and happiness as one of mankind's long-standing chimeras; as Havelock Ellis pointed out 80 years ago, "the early history of this subject is more or less inextricably commingled with folklore practices of magical origin". It still is, and Taberner has legitimately dipped into the rich fields of ancient tradition, magic, herbalism and quackery to provide many telling illustrations of human hopes and credulity, though pornography is unaccountably absent from the index.
